So trusting that the audio board is working as it should and can process the output of the Product Detector, then the problem now is very weak Marker and very weak off air signals and low or no S-meter indication. Dont worry about weak moni at this point.

So this is place I would use RF sig generator and split the problem. Is it on the IF board or the RF board (or both but not likely). If you want to work back from the Audio Board then I would inject 8.830 mhz into the RIF terminal on the IF board and see if you can hear it loud and good S meter indication. If you can then move on to the RF board. If you cannot get back and we can talk about signal injection/tracing on the IF board.

Inject 8.830mhz at Conn 6 on IF board. You dont need any modulation. -73dBM/50uv should give approx S6. -53dBm/500uv should give approx S9. -33dBm/5mv should give approx +20 over.

Terry K9TW

Can you guess that the new rectifier board, with the added 100K resistor for the missing side-tone bias connection, is working perfectly?

All voltages, 9 to 900 (well, 852, actually, but that rounds UP to Got 900!) are present and accounted for.

Fan is running, filaments are lit, lamps are lit. Low-level Brownian noise on the headphones, that nice, clean static hiss. Changes tones when going from USB to LSB to CW to Tune, too. Markers are there, clean and LOUD. Got a weak signal for WWV with just the dummy load for an antenna, too. The receiver sounds FANTASTIC. Been much too long since I had headphones on....

Now, the bad news.

The meter switch does nothing,

All settings, it just sits right at about 850 on the HV scale. It's as if it was hard-wired directly to the HV line and the switch was bypassed or something.

No, wait a minute...Now THAT'S odd.

In all meter switch positions, the RF Gain pot will move the needle up or down scale, in the INVERSE direction. Fully CCW is pegged to the right (full-scale); fully CW is near zero deflection. It's not stuck on HV at all, the 850 level on the HV scale was just a coincidence. Looks like it's measuring RF into the receiver somehow, but backwards.

This couldn't be simple. After all this fol-de-rol, it couldn't ALL just work again.

Sigh.

OK. Best get started. Advice? Where to start? Again, I have not and AM NOT GOING TO touch the transmitter section until receive and all the ancillary bits are working properly.

One Thing At A Time. (Ain't I got enough troubles??)

Just for a record of all the settings:

SG is off

REC mode
WIDE bandwidth
MAN vox setting
Noise blanker is off

AGC is off

MODE is presently in USB, but the meter doesn't change in any mode.
VFO is in the 20m band around 200 on the dial.
Function is on VFO
FIT is off, and the RIT pot is centered.
Processor is off
CAR is at 1200
AF and RF Gain at 1200

FIX CH on #1 spot, and who cares, does nothing in any but FIX Function switch settings of course.

LOAD at 1200
PLATE on the 20M mark (about 1300)
DRIVE at 1200.

Meter switch in all positions, nothing changes. Currently with RF gain at 1200 it shows about 850 on the HV scale/170 on the mA scale.

Oh, almost forgot. POWER is on (duh).

44581. Kenwood Hybrid Net Update (September 15, 2013)

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-15 19:41:36 UTC
From: Mark Gilger
Topic: 44581 Message: 44581

The Saturday□s net on 40 meter had 17 stations
checking in under fair band conditions. There
were 7 new check-ins, KB1ZOJ, W2EWK, K2QU,
W4XRP, W4IBK, KF4UKC, KD8FPS. Out of those, there was:

3 running TS-520(x)
1running TS-530(x)
1 running TS-820(x)
3 unning TS-830S
0 running TS-900

Jimmy, WB2KNR ran the net and was running his
TS-520. The rest were running non hybrids of one model or another.

The Sunday□s 20 meter net had 15 stations
checking in under good band conditions. He had 5
new check ins, KB6TSQ, KA6OCA, WN7L, AK6E, and W5CNW. Out of those, there was:

3 running TS-520(x)
0 running TS-530(x)
4 running TS-820(x)
2 running TS-830S

I was running my TS-940. The rest were running
non hybrids of one model or another.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins

November 2012, Saturday☐s, net total = 47, Sundays total = 20
December 2012, Saturday☐s, net total = 74, Sunday☐s total = 70
January 2013, Saturday☐s, net total = 93, Sunday☐s total = 87
February 2013, Saturday☐s net total = 103, Sundays total = 87
March 2013, Saturday☐s, net total = 112, Sunday☐s total =39
April 2013, Saturday☐s net total = 52, Sunday☐s total = 29
May 2013, Saturday☐s net total = 45, Sunday☐s total = 50
June 2013, Saturday☐s net total = 30, Sunday☐s total = 27
July 2013, Saturday☐s net total = 63, Sunday☐s total = 41
August 2013, Saturday☐s net total = 82, Sunday☐s total = 50
September 2013, Saturday☐s net total = 31, Sunday☐s total = 35 (Month to date)

44582. VTVM at an Antique Store?

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-15 19:44:20 UTC
From: Chris Maness
Topic: 44582 Message: 44582

Working on my TS-520s, and I was admonished to purchase a VTVM. It just so happens I came across one at an antique store. I am not sure if it's worth it though. The guy wants $30 for it. It seems to work intermittently. There is no corrosion from the Ohm scale battery and it comes with test leads. Im not sure if the probe is an RF probe or not. It has a switch that says DC on it. The model is Heathkit IM-11. What do you guys think? I am not necessarily looking to fix another piece of equipment before I get to fixing the radio.

Input appreciated.

Thanks,
Chris KQ6UP

Will,

The meter switch doesn't function in receive mode, only when in transmit where it selects the functions listed around the switch. In receive the meter is always is an "S" meter, measuring the strength of the incoming signal. As for the RF gain, it is operating correctly. Turning the RF gain fully CW (Clock Wise) makes the receiver the most sensitive. Turning the RF control toward fully CCW (Counter Clock Wise) makes the receiver progressively less sensitive. The needle on the meter increases from zero (or near zero) indicating maximum sensitivity to the maximum on the scale as the receiver is made less sensitive by the counter clock wise rotation of the RF gain.

Have you connected an antenna (or length of wire), turned the RF gain fully CW, and tried to listen for any signals? If just using a piece of wire I suggest trying 80M, 40M, or 20M for your test since.

Let us know what you find. I believe you will be pleasantly surprised!

CRAP.

Stupid me. HAD to complicate things.

Turned the radio off. Plugged in the DG-5 freq display.

Turned the radio on.

POP.

Meter light and tube filaments are all that is left. DEAD.

And I smell that something burnt.

Fuses are fine. Has to be that rectifier board again.

.
.
.

I am going to lose

what little I have left

of my mind.

That's not the RF probe, most likely.

Will he sell it to you with a return option if cleaning the switches and pots inside don't fix the intermittent problem?

$30 is a bit steep, but not too far out, if it works.

Sounds (from what little info we have here) that it's mostly intact. If you can get it working briefly in the store, see if it will (with the probe in the DC setting) measure somewhere near correctly the voltage from a battery, an AA or D or 9volt cell, or whatever.

If it does, with the scale set on an appropriate level (15V or 5V or 1.5V or whatever) then it more than likely just needs a good cleaning and calibration. The manuals for that model are pretty ubiquitous, I think the BAMA archive has it. Almost positive.

I would be tempted to cruise around eBay a bit just to see how their prices compare. Don't limit yourself to the IM-11. There are a bunch of different makes/models out there. I see them at flea markets a lot (and I mean general flea markets not hamfests). Plenty of them out there.

OK. Thanks for that. Wondered if that was the way things were, though RF gain working as an attenuator is a labeling issue. Didn't know it was mis-labeled, since AF Gain works as a GAIN control (higher is louder) and not an attenuator (higher is lower).

So. It WAS working correctly. Bloody good.

But now there is nothing on the 14v output on the rectifier board (which is the one I just replaced). Bloody figures.

Got all the high voltages, just no low-voltage for biasing EVERYTHING else.

Which was the ORIGINAL problem, though the board was burned to a crisp in that area, that time. The screw which had fallen out into the chassis was shorting the 800V doubler to the 14V bias line.

This time there is nothing visibly wrong. Probably popped a diode, will be checking it soon.

And I apparently have a bad DG-5, with a dead short in the DC input lines, to work on when I get the radio going.

Oh, carp. crap. carp. I wanted to be FINISHED with this thing.

Chris,

The IM-11 is a decent VTVM. I have the IM-18, the successor to the IM-11. The probe with the switch selects between DC measurements and AC voltage/resistance. In the DC position a 1 megohm resistor is placed in series with the probe tip to provide an 11 megohm input resistance (the remaining 10 megohms is inside the meter) as well as to isolate the meter from the tested circuit. In the other position the resistor is bypassed so the meter can measure AC voltage and resistance. Those original Heathkitprobes are difficult to find separately and they often do not come with the
meter.

It seems to me that $30 is a bit much for an IM-11. I have obtained a few RCA/VIZ Senior VoltOhmyst WV-98C meters for $25 and they have a larger meter. Check QTH, QRZ, eHam, and ebay before you pluck down your money. OTOH, if the meter is in excellent physical condition and the probe is complete and working properly (as I said above, they are difficult to find) then it might be a good idea to get it. After all, you are in a position to see the meter and check it before you purchase so that is a good thing. Since you had it open to check the battery contacts you were able to inspect the build quality. Was it good? If not, I would leave it and look for another. I built my IM-18 in 1969 and it is still going strong.

You say it works "intermittently". Please explain. Is it making erratic measurements on a known, stable voltage? Are you seeing unstable ohm measurements? Are the pots "scratchy" or have dead spots? If any of these is the problem I would clean the probe jack and plug as well as apply DeoxITto the switch contacts and use
FaderLube on the pots. Regardless of what VTVM you end up with you should do this maintenance so you know you have a reliable meter. If, however, the pots have dead spots it may be a damaged section that will require that the pot be replaced. You won't be able to determine that without a bit of troubleshooting.

Consider that it DOES HAVE the 11M AC/DC probe. Most of the Heath meters found on eBay have the probes missing.

The IM-11 is as good as any vintage VTVM other then the HP meters. And the manual is available.

I went ahead and picked up the meter. The soldering in the unit looked very well done. I gave it a bath in DeoxIT. It looks like the probe was the source of the problem. Very heavy black oxidation/carbon build up on the contacts inside the probe switch. It is mostly working after cleaning. The meter itself seems to be working, but it does need to be calibrated. I now have a VTVM. I am off to calibrate it.

Topic: 44582 Message: 44592

The probe itself is NOT "11 meg", it's a "1 meg" resistor in series with the tip making it a "1 meg probe". The 1 meg probe is required only when measuring DC voltages. AC and Ohms, the probe has no resistor in series with the tip, it's just a wire from the tip to the input of the VTVM.

The original switchable probe had a rotating switch on the tip. Rotate the switch to "AC/Ohms" and the probe has no resistor in series with the tip. Rotate the switch to "DC" and the 1 meg resistor is in series with the tip.This is the same with ALL VTVMsthat have switchable probes.

If the VTVM does not have the probe then you can make your own probes. I found old/vintage thin diameter DC meter probes with the removal nut on the tip end. This allows you to install a 1meg resistor in series with the tip. I used RG-8X coax. You can see this type of probe on my basic test equipment video at the following link:

http://www.n6wk.com/w5rkl/Basic%20Test%20Equipment/

There are other ways to make the probes without having to search high and low for the original probe, they are difficult to find.

Actually, $30 is not a bad price for the VTVM if it working. I have 4 VTVMs andonly 1 had to be fixed, an AC volt meter. The tubes inside are usually 6AL5 dual diode and a 12AU7 dual triode. These tubes, if they glass envelope is not cracked due to abusive handling, don't need replacing. All of the tubes in my VTVMs are over 40 years old and they work just fine. You should not have to replace any of theresistors, they are typically precision resistors.

If you wait for eBay or some other auction/sales web site, you may get one cheaper but the shipping cost could easily bring the total cost upto and sometimes higher than the $30.

I went ahead and picked it up. It is working 100% now and also calibrated. It looks like the issue with the probe is that high current went through it it at some point and deeply pitted the switch contact inside the probe. It is mostly working now, but can be a bit finicky. The meter is very accurate across different ranges now that it is calibrated. I am quite impressed with it.

Thanks, guys

>

Here is the table of data:
CAR= | V=
0 | .360V
1 | .365V
2 | 1.26V
3 | 2.20V
4 | 3.45V
5 | 4.60V
6 | 5.50V
7 | 7.00V
8 | 8.00V
9 | 9.00V
10 | 9.00V

Something aint right in paradise. A strange thing that happens is I get no voltage in REC at CAR=0 (that seems normal). However, once I get to setting 2, this crazy high voltage shows up weather I am in REC or SEND. Measured with a VTVM I found at an antique store this afternoon on my way home from church. I cleaned and calibrated it. I don't have an RF probe for it yet.

It looks like the voltage divider es no dividing.

Terry:

Thanks for the insight and next steps. I'm very careful around the HV caps and always make extra sure everything is discharged before poking around in there. I'll coordinate performing these steps with Jason and report back. If should be educational to take a look around inside.

Subject: RE: Re: [TS-520_820_530_830] New Ham, Tuning issues

Brian:

No problem with using a Key to load the rig. Just not necessary when bench testing a rig. The 830 manual contributes to this when early on they tell you to connect dummy load or antenna and connect a Key and then flip to Send and check resting plate current. However they fail to tell you to press the Key or close the slider if a straight Key. Later under Transmission section under CW header they tell you again to install a Key. Poorly written.

When you turn the Plate Load cap control CW off the full CCW position and you see the RF output power on the wattmeter go down do you then immediately adjust the Plate Tune capacitor to try to bring the RF output power back up?

Anytime the Load cap is moved open or closed you need to make a slight adjustment with the Tune capacitor to restore the tank to resonance. What happens when you do this?

Typically once the reactance of the Plate Load capacitor is close to the impedance of the load (antenna or dummy load) opening the plates (CW) any more usually does not result in anymore RF output on the wattmeter. You reach a point where opening the plates more does not result in coupling any more load. The final tubes just cannot supply any more RF Line current to the Tank.

There is no doubt that loading on 40 meters into a 50 ohm dummy load you should not be at maximum RF output with the Plate Load cap full CCW (plates fully meshed). As you suggest it is not "normal". You know that from your own TS-830.

As I mentioned this is indicative of bad fixed padder caps that are switched in on the lower bands. The reason that this is necessary is if they installed an air variable capacitor that had the necessary high level of capacitance on the lower bands it would then have a minimum capacitance with the plates completely open that would be far too high to function on higher bands. 10 meters is the biggest challenge for the designers. Same for the Plate Tune capacitor.

If you get time it would be good to see if it loads normal on 15 and 10 meters. I would try loading on all the bands and make a chart of how it behaves. Where does the plate Load cap end up for approx 100 watts output at 200ma Ip.

One other thing you should look at if comfortable is the main RF plate choke and the small VHF choke at a right angle at its base and the rf bypass cap at its base. If these show signs of overheating then will need to be replaced. The by pass cap can actually physically split the case open.

Need to have rig unplugged and let set for awhile to led bleeders discharge the HV filter caps. Then remove PA cage cover. Then connect ground jumper from top of plate choke and ground for a few seconds. Now safe to use a good flashlite and inspect these items.

I would also look at both capacitor shaft couplers at the PA cage and make sure screws are tight. Can also watch the travel and make sure full open and full close align with markings on the front panel.

Hi Terry:

Ah ha. I am a CW op so I always have had a key plugged in (but no mic). Anyway, with a key plugged in you don't get any output with the alternate procedure without closing the key for obvious reasons. I've been so used to how the radio responded when I switched over from tune to CW with a key connected that I ended up thinking the key was necessary. My bad. For me the long procedure from the manual works fine since I always have the key connected and normally have the radio in VOX mode (to save wear on the send switch) but I have a better understanding now. Thank you. I will also study the diagram to try to better understand the relationship between the load capacitor and antenna load.

This will also help Jason since I took him through the long procedure from the manual that uses a key. He can just unplug his keyer and will be able to move from tuning to loading once he has the drive and plate a resonance (peaked and dipped) without all of the additional gyrations.

Questions: This still leaves Jason's TS-520's issue with load. Even though I was using the long procedure with the key, I think the results are still accurate. He is getting a maximum output of 70w at 200ma with the load at min (fully CCW) and reducing the load capacitance (increasing the load/turning load CW) actually reduces his output. This isn't normal, right? I can simulate this on my TS-830 but it pains me. If I intentionally turn the load up too much, output falls off as I increase the load. So...I think in Jason's TS520 it is as if even at maximum capacitance (minimum load) he doesn't have enough to balance against the 50 ohm dummy load---resonance is off the minimum end of the load. Does that sound like a reasonable conclusion? Is the next step for us to try the tune up procedure on all bands and report back (your 10m suggestion from before) or is there something else that we should check first?

Thanks,
  Brian (and Jason)

Subject: RE: Re: Re: [TS-520_820_530_830] RE: New Ham, Tuning issues

You dont need the key or vox or any of the gyrations you are putting your self thru to load your TS830.

The reason Ip indicates approx 60ma when you switch from Tune to CW mode is that you have the plates meshed on the Plate load cap and you are shunting the RF current around the dummy load and circulating it in the Tank.

It is OK to crack the Plate Load control open a little at initial loading so you can see 70 or 80 ma or so if that helps you.

At this point with plates fully meshed you have maximum capacitance and lowest capacitive reactance so the RF current in the tank is going to like to flow thru the plate load cap and not thru the dummy load. Sometime look at formula for Xc and you will see it is an inverse relationship. It will help you understand what I am telling you.

OK --You havent started tightening up the coupling yet and shifting the tank circuit RF circ current to the dummy load resistance. Each time you open the plates of the Load cap a little more you are decreasing the capacitance and increasing the capacitive reactance XC. This allows more current to flow in the dummy load resistor or the antenna.

When you get to full load you will have opened the Plate Load capactor to the point that the XC is approx equal to the dummy load or antenna resistance. At this point you will have used half of the stored energy in the tank and there will be equal RF current flowing thru the Plate load capacitor and the dummy load resistor. At that point with 100 watts output power there will be approx 1.4 RF amps flowing thru the Plate load cap and 1.4 RF amps flowing thru the 50 ohm dummy load.

This is all simple ohms law for parallel resistors, but not too many folks really understand what they are doing or how it works or have just never given it any serious thought.

After you make that initial plate current dip in Tune mode you do not need to do any more dip and load procedure. Only reason you do this initial dip is to get the tank circuit adjusted close to resonance so when you go to CW mode and apply full screen grid voltage to the finals you dont peg the IP meter if the tank is tuned off resonance. This could damage your finals if left keyed too long at this high Ip level.

Read the very last note in the TS-830 loading procedure. It tells you after they have taught you dip and load you dont have to use it as it isnt best or easiest way to load a Class AB1 linear amp!

It directs you to place meter in RF position and Flip to Send and alternately adjust the plate Load and Tune controls for maximum indicated relative power (RF voltage).

With your wattmeter in line leave your TS830 meter in IP. Now after making that initial plate current dip in Tune mode flip to Send in CW mode and alternately adjust Plate Load and Plate tune controls for approx 100watts output.

Your wattmeter will be far more sensitive to any changes you make than your IP meter. You will quickly be able to find the combination that gives you max rf output power. Take a quick look at IP and it should be close to 225ma. If a little over dont worry about it as 265ma is the real limit.

Lastly, if you are having to increase the Car level at the late stage of tuning you are not setting it high enough in the early Drive control peaking step. There is no reason to have to do this. When you peak the Drive give yourself something to look at. If you peg the ALC meter just reduce the Car level pot to get it off the peg.

I have found a source for them in the U.K. Some guy has a bunch of NOS V06B's, and they're rather low cost. I'm going to place an order with this guy, and I would like to know if anyone wants a few for their junkbox or to repair a radio. They're going to cost me less than a quarter each. More like a dime, actually, before postage. That's going to cost more than the parts, I guess.

IF THE GUY RESPONDS, I don't want to get just ten of them (minimum quantity), if anyone else can use some.

Let me know how many you'd like, and I'll add them to the order. When they get here I'll mail them to whomever says they want some. U.S. postage will be just a first-class stamp. Other countries will be whatever it comes to, they're tiny and will go in an envelope. Maybe a buck for most places, buck and a half at the outside.

I'll divide the total cost when they get here. and let you know how much each precisely, but figure on a quarter or less each, and the price of a postage stamp.

Topic: 44446 Message: 44598

Dumb question. I know, I'm full of those.

I've looked at the spec sheet for the V06B. I know the other diodes and even some of the resistors in these radios were chosen for very specific reasons: to act as fuses, in the case of some of the resistors; for their switching characteristics, and so on.

Is there ANY such reason of which I am unaware which would make replacing these with just about ANY 100 volt PIV (or higher) silicon diode a bad idea?

I'm not talking about slapping a kilovolt PIV high-power rectifier in there, just something easily available so I don't have to wait for postage from London, England.

OK as I understand what you are saying you are speaking in the mic and getting some flicks of ALC and when you increase the mic gain more you reach a point where you lose the flicks of ALC and as you increase the mic gain past that spot you get flicks but much higher than you would like to see. Is this correct?

Try this to see if you are losing ALC indication or losing modulation.

Flip the meter to Ip or RF and watch the meter as you perform the same increase in mic gain. See if at the same place you were losing ALC you also lose Ip or RF indication. If you do then you know it is likely a bad spot on the mic gain pot. The peaks on IP and RF meter position will be different than what you observed on ALC but dont worry about that.

If so, you lose Ip and RF like you do ALC I would try cleaning the mic gain pot as a first step.

Also what kind of ALC indication are you trying to attain on voice peaks?

What position are you trying to run the Mic gain at (3, 4, 5, 6)?

I think $30 is reasonable for a unit that basically works and comes with the probe. You will find that the circuits for the various HK models that use the 6AL5 and the 12AU7 are almost identical. There should be a filter cap in there of 16uF@150V. I would replace that one. I don't think 16uF is common any more but a 22uF should be fine.

I went ahead and picked up the meter. The soldering in the unit looked very well done. I gave it a bath in DeoxIT. It looks like the probe was the source of the problem. Very heavy black oxidation/carbon build up on the contacts inside the probe switch. It is mostly working after cleaning. The meter itself seems to be working, but it does need to be calibrated. I now have a VTVM. I am off to calibrate it.

You should never have more than approx 0.50vdc at BM terminal. The Bal Mod diodes are germanium so turn on is around 0.25 to 0.30vdc for them.

Need to look at Resistor R21 18k close to the CW terminal post. You can use a straight pin. I use 2 inch corsage pins or floral arrangement pins with heat shrink over most of the pin. These have a pearl ball on the top of them to make handling good. I then clip a mini-grabbber test lead near the head and to the plus lead of my DMM or VTVM test leads. This allows you to probe at the hole where resistor leads enter the component side of the board.

You should find on one side of R21 you have variable voltage from 0 to 9vdc and on the other side from 0 to 0.50vdc. It appears that R21 is shorted which is very unusual.

You will have to fold the Gen Board over to replace R21 so at that time I would also check the balanced modulator diodes D1, D2, D3, D4 given you have reported distorted audio.

Since you have to lift one lead of each diode to check them I would just go ahead and replace all 4 of them. Do not use Silicon switchers like 1N914 diodes. 1n60s and 1n270s are fine. Mouser will have and Scotts Electronics who sells Crystal radio parts is a good supplier of the germanium signal diodes.

I know of no resistors designed to act as fuses? A resistor makes a very poor fuse.

Not trying to be too picky but you are not getting 200ma. None of the meter scales mean anything when peaking the Drive control. Just want to make sure you dont think you are reading Ip at this step. What you are seeing it that you are getting the meter indicator to deflect and peak at a little more than 1/2 scale for the particular Car Level pot setting you are using. This is essentially relative RF drive level. Any place on the meter where you can peak it with the Drive control means you have maximum RF drive voltage swing at the control grids of the 6146 finals.

No this does not sound like a Driver tube problem.

It is possible the 12BY7A tube failed completely, but typically the emission just falls off gradually. This sounds more like an intermittent. Maybe bad solder connection at tube socket or bad band switch contacts.

If you have no indication on one or two bands and good indications on other bands then it is not the tube or the tube socket solder connections. It is most likely band switch contacts problem.

Yesterday did you have good ALC indication while peaking the Drive control on all bands?

Today are you saying you now have no ALC indication on any bands even with the CAR Level pot full CW?

Terry K9TW

OK as I understand what you are saying you are speaking in the mic and getting some flicks of ALC and when you increase the mic gain more you reach a point where you lose the flicks of ALC and as you increase the mic gain past that spot you get flicks but much higher than you would like to see. Is this correct?

Try this to see if you are losing ALC indication or losing modulation.

Flip the meter to Ip or RF and watch the meter as you perform the same increase in mic gain. See if at the same place you were losing ALC you also lose Ip or RF indication. If you do then you know it is likely a bad spot on the mic gain pot. The peaks on IP and RF meter position will be different than what you observed on ALC but dont worry about that.

If so, you lose Ip and RF like you do ALC I would try cleaning the mic gain pot as a first step.

Also what kind of ALC indication are you trying to attain on voice peaks?

What position are you trying to run the Mic gain at (3, 4, 5, 6)?

Hi Dave,

Thank you for your supportive comments on the videos. I enjoy making them and hopefully the members are learning something from them.

I wouldn't call the room "portable" (see my qrz.com bio page). The shack is a 10' x 20'separate building in the back yard. The operating position at one end while the service benches are along the back wall and opposite end. The shack is a mess at the moment, needs a thorough cleaning.

Thank you Don for the supportive comments on the videos.

You can download the videos by "right clicking" on the video link then select "Save Link as...". When the save window opens, select a location to save the video then click the "SAVE" button on the bottom right of the window. The basic test equipment video is 62meg so it will take some time to download onto your computer.

Once the video is saved to your computer, simply double click on the video icon or right click on the video icon and select Play. Windows Media Player should open and play the video for you.

I don't use Google's Chrome so I can't comment on that browser (I used Firefox).

You can change the video viewer used by your browser by changing the browser's application options for different types of files. As I said, I don't use Google Chrome so I can't comment how to do this in Chrome. However, Firefox file types can be changed in the Firefox Option's "Application" tab.

You can also determine what video viewer your operating system is using to display video files by right clicking on the video file's icon then select "Properties". When the properties window opens look for the "Open with" statement at the top of the properties window. That tells you what the operating system's video player is using to view video files saved on your computer. It may not be the same video viewer your browser is using.

Don, you can duplicate the video voltage calculations AND the voltage
and current measurements yourself. I highly recommend youdo that. You
don't need the $85 self power breadboard I used. Acouple of 6 volt
lantern batteries connected in series will give you 12VDCas a power
source. A few resistors, they are cheap, and a simple digital volt
meterwill do fine. You said you are a "visual" person. Well if that's
true then I recommend you do the samething I did by obtaining the simple
components and do the experiment yourself! Change the resistor values,
add resistance to the circuit, so you will see what happens. Change
voltage levels by using one battery to see what changes occur by
lowering the DC voltage!This is how you learn!

Wes

Not trying to give you a hard time. I suspect you are just repeating what you have heard or read. Many people believe that the 5 ohm cathode resistors are fuses. No amount of logic will change their minds.

They are meter shunts used for measuring plate current and not fuses. You never want to open circuit the cathode of your final tubes. You would see cathode potential rise which could damage your panel meter if the moment of the fault had not already done so.

Couple of common ways to measure plate current:
1. Cut the 900vdc final tube anode B+ line and insert a 500ma meter in series. This will work just fine but is not a safe option. You would have 900vdc in the meter and would never want anyone to be able to touch the face of the meter. Manufacturers who used this method back in the day used special designed meters with high dielectric strength and/or placed the meter movement behind a glass plate on the rigs front panel. Can you imagine a linear amp with 2800vdc on the IP meter within your reach on front panel! Well it was done.

2. Install a low value of resistance in the final tube cathode circuit to ground. Take a dc current meter and place a meter multiplier resistor in series with it and use the voltmeter method to measure current. The value of this cathode meter shunt typically will range from 0.10 ohm, .50 ohm, 1.0 ohm, 2.0 ohms to 5 ohms we see in our hybrids. Yaesu, Heath, Drake, Kenwood and others use this method.
A ma or ua dc current meter with appropriate sized series resistor is then used to measure the IR drop across this cathode resistor that occurs when plate current flows thru it. The higher end rigs use a ua meter movement that cost a little more. Your meter is a 500ua movement that will see 0.40vdc full scale deflection. This corresponds to 1.75vdc drop across the 5 ohm cathode resistors at 350ma of plate current. Of course will never see 350 ma. At 225ma Ip your meter will be measuring approx. 1.125vdc.

So what about the cathode resistors also serving as fuses? First of all you never want these resistor to blow open. To do so puts your panel meter at great risk of damage.
If Kenwood wanted them to act as fuses and blow open under some fault condition they would have installed some meter protection. There is no meter protection.

1. Why would they blow open? If you loaded rig to 350ma and put brick on the key the 5 ohm cathode resistors could dissipate this load for hours on end with no ill effect. These are 2 watt rating. P= I squared R so P= .350 x .350 x 5 = 0.61 watts. Carbon resistors can withstand many many times over current for a long time before the value will change or resistor fails. They can get so hot you cant touch them and still suffer no ill effects.

2. So what other fault condition would cause them to blow? If a S2001 or 6146 final tube was to arc over and apply 900vdc to the cathode then the resistors would blow instantly and violently. The closest element to the anode is the suppressor grid and it is connected to the cathode so if there is an arc over it is possible to see 900vdc on the cathode for a brief moment. I = E/R or I = 900/5 = 160amps! So ignoring the transformer ESR if a final tube arcs over the cathode resistors will be the only thing limiting the fault current. P=

I squared R. So P = 160 x 160 X 5 = 128,000 watts! So a 2 watt resistor is not going to be able to dissipate this level of power for very long!

3. Back when Kenwood was building these radios they had at their disposal new S2001 and 6146 final tubes. The 900vdc anode voltage that Kenwood employs is more than other rigs typically employ, but a good new 6146 can easily hold off around 2000vdc during a DC hi-pot leakage test. In RF service the anode sees approx 1600 volts P-P swing. So never in their wildest dreams did they envision tube arc overs that would result in 900vdc being applied to the cathode of the tubes. As I said had they projected this type of failure they would have installed meter protection in the radios or perhaps fast blow fuses in the B+ rail.

At the moment of the tube arc over the meter in the IP position would see 900vdc across the cathode resistors. The meter is designed to measure a maximum of 1.75vdc configured as a voltmeter.

If the meter survived the blowing of the cathode meter shunt resistors then there is further risk to it after the resistors are gone. Once the resistors blow open you now have a final tube with an open cathode. At this point the cathode will immediately and quickly start to rise toward the screen grid potential and in a matter of seconds the cathode is now at over 100vdc to gound. So now your 1.75vdc panel meter is trying to measure over 100vdc.

The only thing that prevents damage is the operator on hearing the big bang will unkey the rig and the Aux relay now changes the meter over to the S-meter function and it is no longer looking at this high cathode voltage. However, if the Op tries to key the rig again and flips to send and places meter in Ip position for an instant the meter is again exposed to over 100 vdc. Once meter is connected it closes the path from cathode to grd and the 100 vdc is pulled down by the series combo of the 3k multiplier and the 800 ohms of the meter movement. All of this is very hard on the meter.

So cathode meter shunt resistors are just that.... resistors. They are meter shunts and not fuses..

If you were thinking of other resistors acting as fuses be curious which ones you have in mind.

For more on this see W8JI website where he discusses the subject more in depth. .

Subject: RE: Re: [TS-520_820_530_830] New Ham, Tuning issues

Brian:

No problem with using a Key to load the rig. Just not necessary when bench testing a rig. The 830 manual contributes to this when early on they tell you to connect dummy load or antenna and connect a Key and then flip to Send and check resting plate current. However they fail to tell you to press the Key or close the slider if a straight Key. Later under Transmission section under CW header they tell you again to install a Key. Poorly written.

When you turn the Plate Load cap control CW off the full CCW position and you see the RF output power on the wattmeter go down do you then immediately adjust the Plate Tune capacitor to try to bring the RF output power back up?

Anytime the Load cap is moved open or closed you need to make a slight adjustment with the Tune capacitor to restore the tank to resonance. What happens when you do this?

Typically once the reactance of the Plate Load capacitor is close to the impedance of the load (antenna or dummy load) opening the plates (CW) any more usually does not result in anymore RF output on the wattmeter. You reach a point where opening the plates more does not result in coupling any more load. The final tubes just cannot supply any more RF Line current to the Tank.

There is no doubt that loading on 40 meters into a 50 ohm dummy load you should not be at maximum RF output with the Plate Load cap full CCW (plates fully meshed). As you suggest it is not "normal". You know that from your own TS-830.

As I mentioned this is indicative of bad fixed padder caps that are switched in on the lower bands. The reason that this is necessary is if they installed an air variable capacitor that had the necessary high level of capacitance on the lower bands it would then have a minimum capacitance with the plates completely open that would be far too high to function on higher bands. 10 meters is the biggest challenge for the designers. Same for the Plate Tune capacitor.

If you get time it would be good to see if it loads normal on 15 and 10 meters. I would try loading on all the bands and make a chart of how it behaves. Where does the plate Load cap end up for approx 100 watts output at 200ma Ip.

One other thing you should look at if comfortable is the main RF plate choke and the small VHF choke at a right angle at its base and the rf bypass cap at its base. If these show signs of overheating then will need to be replaced. The by pass cap can actually physically split the case open.

Need to have rig unplugged and let set for awhile to led bleeders discharge the HV filter caps. Then remove PA cage cover. Then connect ground jumper from top of plate choke and ground for a few seconds. Now safe to use a good flashlite and inspect these items.

I would also look at both capacitor shaft couplers at the PA cage and make sure screws are tight. Can also watch the travel and make sure full open and full close align with markings on the front panel.

Terry K9TW

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Hi Terry:

Ah ha. I am a CW op so I always have had a key plugged in (but no mic). Anyway, with a key plugged in you don't get any output with the alternate procedure without closing the key for obvious reasons. I've been so used to how the radio responded when I switched over from tune to CW with a key connected that I ended up thinking the key was necessary. My bad. For me the long procedure from the manual works fine since I always have the key connected and normally have the radio in VOX mode (to save wear on the send switch) but I have a better understanding now. Thank you. I will also study the diagram to try to better understand the relationship between the load capacitor and antenna load.

This will also help Jason since I took him through the long procedure from the manual that uses a key. He can just unplug his keyer and will be able to move from tuning to loading once he has the drive and plate a resonance (peaked and dipped) without all of the additional gyrations.

Questions: This still leaves Jason's TS-520's issue with load. Even though I was using the long procedure with the key, I think the results are still accurate. He is getting a maximum output of 70w at 200ma with the load at min (fully CCW) and reducing the load capacitance (increasing the load/turning load CW) actually reduces his output. This isn't normal, right? I can simulate this on my TS-830 but it pains me. If I intentionally turn the load up too much, output falls off as I increase the load. So...I think in Jason's TS520 it is as if even at maximum capacitance (minimum load) he doesn't have enough to balance against the 50 ohm dummy load---resonance is off the minimum end of the load. Does that sound like a reasonable conclusion? Is the next step for us to try the tune up procedure on all bands and report back (your 10m suggestion from before) or is there

something else that we should check first?

Thanks,
Brian (and Jason)

Subject: RE: Re: Re: [TS-520_820_530_830] RE: New Ham, Tuning issues

You dont need the key or vox or any of the gyrations you are putting your self thru to load your TS830.

The reason Ip indicates approx 60ma when you switch from Tune to CW mode is that you have the plates meshed on the Plate load cap and you are shunting the RF current around the dummy load and circulating it in the Tank.

It is OK to crack the Plate Load control open a little at initial loading so you can see 70 or 80 ma or so if that helps you.

At this point with plates fully meshed you have maximum capacitance and lowest capacitive reactance so the RF current in the tank is going to like to flow thru the plate load cap and not thru the dummy load. Sometime look at formula for Xc and you will see it is an inverse relationship. It will help you understand what I am telling you.

OK --You havent started tightening up the coupling yet and shifting the tank circuit RF circ current to the dummy load resistance. Each time you open the plates of the Load cap a little more you are decreasing the capacitance and increasing the capacitive reactance XC. This allows more current to flow in the dummy load resistor or the antenna.

When you get to full load you will have opened the Plate Load capactor to the point that the XC is approx equal to the dummy load or antenna resistance. At this point you will have used half of the stored energy in the tank and there will be equal RF current flowing thru the Plate load capacitor and the dummy load resistor. At that point with 100 watts output power there will be approx 1.4 RF amps flowing thru the Plate load cap and 1.4 RF amps flowing thru the 50 ohm dummy load.

This is all simple ohms law for parallel resistors, but not too many folks really understand what they are doing or how it works or have just never given it any serious thought.

After you make that initial plate current dip in Tune mode you do not need to do any more dip and load procedure. Only reason you do this initial dip is to get the tank circuit adjusted close to resonance so when you go to CW mode and apply full screen grid voltage to the finals you dont peg the IP meter if the tank is tuned off resonance. This could damage your finals if left keyed too long at this high Ip level.

Read the very last note in the TS-830 loading procedure. It tells you after they have taught you dip and load you dont have to use it as it isnt best or easiest way to load a Class AB1 linear amp!

It directs you to place meter in RF position and Flip to Send and alternately adjust the plate Load and Tune controls for maximum indicated relative power (RF voltage).

With your wattmeter in line leave your TS830 meter in IP. Now after making that initial plate current dip in Tune mode flip to Send in CW mode and alternately adjust Plate Load and Plate tune controls for approx 100watts output.

Your wattmeter will be far more sensitive to any changes you make than your IP meter. You will quickly be able to find the combination that gives you max rf output power. Take a quick look at IP and it should be close to 225ma. If a little over dont worry about it as 265ma is the real limit.

Lastly, if you are having to increase the Car level at the late stage of tuning you are not setting it high enough in the early Drive control peaking step. There is no reason to have to do this. When you peak the Drive give yourself something to look at. If you peg the ALC meter just reduce the Car level pot to get it off the peg.

Is measuring across CM and CV equivalent? I did that yesterday and got
exactly 18k.

Are you referring to R21 on the GEN board? That is a 10k resistor not
directly connected to the modulator bridge. It connects to Q7 on my
schematic. Yesterday afternoon I measured R53 to be 18k exactly since it is
part of the voltage divider circuit that unbalances the balanced modulator.
I don't see a CW terminal that yo referred to, so maybe referring to a
board other than the GEN board.

> You should find on one side of R21 you have variable voltage from 0 to

This should be the same voltage at the BM terminal, correct? Is it also
possible that one of the BM diodes is open since without a load the voltage
divider should go high? I am thinking an open circuit in the BM (one of
the diodes not conducting) would have the same effect as R53 shorting.
Since the diodes conduct at .25V that would load the 18k resistor and
cause a voltage drop across it. If that diode was not conducting the BM
side of the 18k resistor would go high -- especially since I am measuring
18k across that resistor.

Hopefully I am not missing something with R21. If that is the resistor you
intended or maybe you were referring to a different board.

Thanks a Ton Terry,

Some of the links on thewww.n6wk.com/w5rkl/ page are "folders". If the link has a "/" at the "right end" of the link, that indicates a "folder" so don't try to download from that link. Click on the link and the next page willshow the video files.

As I said before, DOWNLOADING the videos to your computer will take some time, it's not instantaneous as some may think. It all depends on your service provider and how busy Gordon's web server is.

I have not experienced the problems you have. I honestly don't know why so many people have these problems with their computers viewing files. I don't have those problems and I use Firefox.

Mike

I totally agree the best way to learn is by doing.Hands on.
My biggest problem is remembering or retaining what i have learnt,so, i put a lot on paper so i can refer back to it.
I think understanding is more important than remembering.
Maybe i have a lazy mind[bit dyslexia too] as i love books,but after reading a few pages i lose my concentration.
I love Youtube as like i said i am more of a visual person and this has opened up the door for me in my learning curve.Show me. :-)

https://www.youtube.com/watch?v=ZBbgiBU96mM

http://www.youtube.com/channel/UC2DjFE7Xf11URZqWBigcVOQ/videos

I have a NRI Electronic design Laboratory trainer i picked up real cheap.It has no manual,but pretty straight forward on it's functions
It has +12/15 volts and minus 12/15 volts plus 5 volts
It also has 5 vpp sine wave,square wave and triangle 8vpp.plus a IC holder on the breadboard.
I plan to do your experiment's and many others over the winter months.
I do appreciate your videos and looking forward to many more.Now if you can just get Terry
making a few.
I am getting a nice assortment of test equipment, but it's not much good if you don't know how to use it,so that's my goal right now.
Hybrids Rule!

Yup.

http://www.k4eaa.com/supersize.htm

Kind of like from Ken K4EAA? Third section / paragraph at the above link?

So Ken is giving out false propaganda? Whodathunkit.

"Kenwood purposely selected these wattages to act as "fuses" in the
event someone did not properly tune and load their rig, and then keyed
it for an extended period. Better to lose a 20 or 40 cent resistor,
than a $125 power transformer!"

So this is precisely where I got my "misinformation."

Now I -am- confused. And I still do not know for certain if a stock
silicon diode is an acceptable replacement for the V06B.

From the look of the schematic you ought to be able to just throw a
one-piece bridge in there instead of four diodes (in bridge
configuration), modulo there being some specific design criterion that
makes discrete diodes, and that particular discrete diode type, a necessity.

Suggestion that maybe you or Terry make a video on
how to neutralize the finals.What to do and what not to do and
the different methods or equipment to use.
We need our own Youtube channel just for the hybrids?

Wes

I knew where this was going when I responded.

Ken is a nice man, a very smart, and talented man. Certainly far more Kenwood Hybrid repair experience under his belt than me. I have sat in his living room on more than one occasion.

On this matter he and I will have to just agree to disagree. I just dont think he has thought this out very well. I mean no disrespect to him, but on this matter yes I believe he is wrong.

Take a poll on this forum of all owners who bought there hybrids new in the 70s and still have them today and many with the original S2001 finals. Ask them how many have ever had a cathode resistor blow open. I think you will find very few if any have ever experienced this failure. I just dont believe there was any common Final Tube fault anticipated at day one that would cause Kenwood to put fuses in the cathode path.

It was not until the rest of us who were not fortunate enough to be able to buy a new Hybrid started reaching for 35 year old 6146 pulls and nos tubes that have been sitting around off gassing on the shelf did we start to see multiple cathode resistor failures.

So my friend your dilemma is which "guru" to follow. Fortunately you are not asking about Prostrate cancer treatment. Hope you never have to. That will really be maddening and frustrating for you and possibly a matter of life or death and not a hobby issue. Like most Google searches on any topic you will find a wide variety of opinions and some cases passionate debate on any technical topic. The challenge then becomes for each of us which "guru" to believe.

Since I am not a "guru" it make no difference to me which belief you espouse. I should have kept my big mouth shut. It was just hard to sit on sideline and see what I consider to be a myth perpetuated and have the new kids run with it. It is of no operational concern to me as I have taken these "fuses" out of the equation for my personal rigs by shunting diodes across them so they should never blow again and my panel meter is protected.

Last word on the subject ask the Heathkit or Drake or Yaesu folks how often their cathode resistor "fuses" blow?

OK there is nothing special about a V06B diode.

Yes I always recommend that you use original replacement parts when you can. I try to do that myself on all customer rigs. I do that because I believe that Kenwood design engineers had a reason for specing each and every component in the radio. For the most part unless there has been an official service bulletin about a component related design error or long field experience has proven other wise so I try to go with original parts.

However as we all know not always possible. Power supply diodes is one area where there is no reason to worry about it. Very easy for us to figure out what goes there. Two main parameters to concern yourself with and they are PIV and Forward Current. So we know the PIV and unless we measure the load on the 14vdc supply we dont know what the current is but I can tell you it is not anywhere close to 1 amp. Something very easy for you to measure when you get if fired back up and put in your notes. Would you guess 200ma or 300 ma or ????

You have to understand the configuration to select the proper diode and folks like NTE have done the work for you. So for the 14vdc bridge rectifier a general purpose 1000piv 1 amp silicon rectifier or a 600piv 1amp silicon rectifier will work just fine. Also as you state a packaged bridge rectifier will work. Sometimes you do have to consider the package when subbing due to space constraints on the board.

So you dont need any fast recovery HV rectifier diodes here or anything else exotic. Just plain old 1n4006 or 1n4007 or NTE 116 or NTE125. Even Radio Shack should have them. Check with Mike W5RKL for confirmation of what I am telling you. RIght now I have too many rigs spinning in my head!

I am sorry too many rigs. I thought we were talking a TS520?

On a TS520S which has a very different Gen board we are talking R53 18k at CV and CM terminals.

At CV you should see 0 to 9vdc. If you do that is good as it means 9vdc is available and that Car level pot is smooth. At CM you should be seeing this problem with high voltage as you rotate the Car pot if R53 18k is shorted.

You could lift the CM lead wire off the terminal post and insert a 18k resistor between the CM post and free end of the lifted wire and see if problem is fixed and run temporarily this way to see if audio problem is cleared up as well. If it is and you dont want to pull the Gen board at this time just to replace R53 could run with temporary R53. Just have to insulate it.

Terry K9TW

You should never have more than approx 0.50vdc at BM terminal. The Bal Mod diodes are germanium so turn on is around 0.25 to 0.30vdc for them.

Yes, I think herin lies the problem.

Need to look at Resistor R21 18k close to the CW terminal post. You can use a straight pin. I use 2 inch corsage pins or floral arrangement pins with heat shrink over most of the pin. These have a pearl ball on the top of them to make handling good. I then clip a mini-grabbber test lead near the head and to the plus lead of my DMM or VTVM test leads. This allows you to probe at the hole where resistor leads enter the component side of the board.

Nice touch with the pins. That is a great tip.

Is measuring across CM and CV equivalent? I did that yesterday and got exactly 18k.

Are you referring to R21 on the GEN board? That is a 10k resistor not directly connected to the modulator bridge. It connects to Q7 on my schematic. Yesterday afternoon I measured R53 to be 18k exactly since it is part of the voltage divider circuit that unbalances the balanced modulator. I don't see a CW terminal that yo referred to, so maybe referring to a board other than the GEN board.

You should find on one side of R21 you have variable voltage from 0 to 9vdc and on the other side from 0 to 0.50vdc. It appears that R21 is shorted which is very unusual. This should be the same voltage at the BM terminal, correct? Is it also possible that one of the BM diodes is open since without a load the voltage divider should go high? I am

thinking an open circuit in the BM (one of the diodes not conducting) would have the same effect as R53 shorting. Since the diodes conduct at .25V that would load the 18k resistor and cause a voltage drop across it. If that diode was not conducting the BM side of the 18k resistor would go high -- especially since I am measuring 18k across that resistor.

You will have to fold the Gen Board over to replace R21 so at that time I would also check the balanced modulator diodes D1, D2, D3, D4 given you have reported distorted audio.

My guess is that one of the diodes that is supposed to conduct to unbalance the modulator either has a bad solder joint or has gone open. However, I am going to defer to you on this since you have far more experience with this radio.

Since! you have to lift one lead of each diode to check them I would just go ahead and replace all 4 of them. Do not use Silicon switchers like 1N914 diodes. 1n60s and 1n270s are fine. Mouser will have and Scotts Electronics who sells Crystal radio parts is a good supplier of the germanium signal diodes.

I have an old school electronics store one town over so I think I am going to stop in and check to see if they have them.

Terry K9TW

Hopefully I am not missing something with R21. If that is the resistor you intended or maybe you were referring to a different board.

Thanks a Ton Terry,
Chris Maness KQ6UP

I was kind of figuring this was one of "those" sorts of disagreements. His is the only place for that particular bit of 'information' that is of any size or popularity.

I will take it under advisement. In the mean time I will try using same-size / same type parts as often as possible.

I have even found a London-based source for the V06B diodes, and I am going to order a few. (Looks like thirty at least, from the people who have contacted me to get added to the order. Need any? Going to cost me about a quarter each. My price = your price, to within a penny or so. Rounding errors. No risk, no cost, until they arrive. And if you stiff me (as if!) I've learned more than that much from your posts to the list.)

But I'm not going to wait a month or six weeks to get those diodes. Local-procured, I've got a friend in the radio repair business, mostly puts radios and radars in squad cars for the area PDs and Sheriffs departments) who likely has four diodes in his parts bin.

Now, a question, or a request for a quick measurement would be more like it. Humour me here, please.

I am very chary of powering this 520SE back on if there is a short somewhere in the system. It failed when I had plugged in the DG-5 freq counter. Flipped the switch and smelled silicon burning. It actually burned off two traces on the underside of the board, one on each side of the diode bridge. AND ate the diodes, they were brown and shattered when I touched them to desolder. I've repaired the traces with wire and solder.

But the counter, when powered from my bench supply, seems to be working fine, used as a frequency meter with my old Eico generator as a signal source.

The request is for a simple resistance measurement across the 12V power socket where you would plug in that freq counter. Positive side to chassis ground. I get 60 ohms, slowly rising as a capacitor (obviously) charges through. Starts at 58.8 on the digital meter, the ~60% charge

happens in about three seconds, and it continues, slowing of course, to just over 60.3 ohms. After that it takes most of a minute to get to 60.4.

Is that the typical resistance there, power off and just sitting? I know it's a meaningless measurement for most purposes, but I was looking for a short or close to it on that line, and it seems quite a bit low. If that were the actual live circuit resistance, that's nearly 5 amps (E/R, R being assumed to be around 14 VDC).

Oh, and one other thing. Is there ANYWHERE, in any format, documentation for the colour code used in this thing? Besides the missing side-tone bias line on an identically-numbered board (that's shoddy engineering management in my opinion - change the board, change the number), the colour scheme on the the replacement board was totally different with the exception of a few (mostly the red, black, and green) wires. Fully half of the connections were to white-with-coloured-stripe wires, which were totally absent on the replacement part.

I'm annotating my working copy of the schematic, and the copies of the circuit board layout drawings, with the colours as I touch things, but that's going to take a LONG time to complete. And I am not a fan of recreating wheels, so if that information already exists somewhere I would sure appreciate knowing about it.

Thanks for taking the time for the email. It's appreciated. And by the way, one sure sign of "guru-hood" is saying you're not one in the face of convincing evidence to the contrary, Sensei.

Hey, Terry:

I noticed you mentioned these steps for a TS-830. I am running a TS-520, does that change any of the above things you suggested? There might have been some confusion earlier about what model of Kenwood was having issues.

Thanks

Jason, K7BOG

Subject: RE: Re: [TS-520_820_530_830] New Ham, Tuning issues

Brian:

No problem with using a Key to load the rig. Just not necessary when bench testing a rig. The 830 manual contributes to this when early on they tell you to connect dummy load or antenna and connect a Key and then flip to Send and check resting plate current. However they fail to tell you to press the Key or close the slider if a straight Key. Later under Transmission section under CW header they tell you again to install a Key. Poorly written.

When you turn the Plate Load cap control CW off the full CCW position and you see the RF output power on the wattmeter go down do you then immediately adjust the Plate Tune capacitor to try to bring the RF output power back up?

Anytime the Load cap is moved open or closed you need to make a slight adjustment with the Tune capacitor to restore the tank to resonance. What happens when you do this?

Typically once the reactance of the Plate Load capacitor is close to the impedance of the load (antenna or dummy load) opening the plates (CW) any more usually does not result in anymore RF output on the wattmeter. You reach a point where opening the plates more does not result in coupling any more load. The final tubes just cannot supply any more RF Line current to the Tank.

There is no doubt that loading on 40 meters into a 50 ohm dummy load you should not be at maximum RF output with the Plate Load cap full CCW (plates fully meshed). As you suggest it is not "normal". You know that from your own TS-830.

As I mentioned this is indicative of bad fixed padder caps that are switched in on the lower bands. The reason that this is necessary is if they installed an air variable capacitor that had the necessary high level of capacitance on the lower bands it would then have a minimum capacitance with the plates completely open that would be far too high to function on higher bands. 10 meters is the biggest challenge for the designers. Same for the Plate Tune capacitor.

If you get time it would be good to see if it loads normal on 15 and 10 meters. I would try loading on all the bands and make a chart of how it behaves. Where does the plate Load cap end up for approx 100 watts output at 200ma Ip.

One other thing you should look at if comfortable is the main RF plate choke and the small VHF choke at a right angle at its base and the rf bypass cap at its base. If these show signs of overheating then will need to be replaced. The by pass cap can actually physically split the case open.

Need to have rig unplugged and let set for awhile to led bleeders discharge the HV filter caps. Then remove PA cage cover. Then connect ground jumper from top of plate choke and ground for a few seconds. Now safe to use a good flashlite and inspect these items.

I would also look at both capacitor shaft couplers at the PA cage and make sure screws are tight. Can also watch the travel and make sure full open and full close align with markings on the front panel.

Hi Terry:

Ah ha. I am a CW op so I always have had a key plugged in (but no mic). Anyway, with a key plugged in you don't get any output with the alternate procedure without closing the key for obvious reasons. I've been so used to how the radio responded when I switched over from tune to CW with a key connected that I ended up thinking the key was necessary. My bad. For me the long procedure from the manual works fine since I always have the key connected and normally have the radio in VOX mode (to save wear on the send switch) but I have a better understanding now. Thank you. I will also study the diagram to try to better understand the relationship between the load capacitor and antenna load.

This will also help Jason since I took him through the long procedure from the manual that uses a key. He can just unplug his keyer and will be able to move from tuning to loading once he has the drive and plate a resonance (peaked and dipped) without all of the additional gyrations.

Questions: This still leaves Jason's TS-520's issue with load. Even though I was using the long procedure with the key, I think the results are still accurate. He is getting a maximum output of 70w at 200ma with the load at min (fully CCW) and reducing the load capacitance (increasing the load/turning load CW) actually reduces his output. This isn't normal, right? I can simulate this on my TS-830 but it pains me. If I intentionally turn the load up too much, output falls off as I increase the load. So...I think in Jason's TS520 it is as if even at maximum capacitance (minimum load) he doesn't have enough to balance against the 50 ohm dummy load---resonance is off the minimum end of the load. Does that sound like a reasonable conclusion? Is the next step for us to try the tune up procedure on all bands and report back (your 10m suggestion from before) or is there something else that we should check first?

Thanks,
Brian (and Jason)

Subject: RE: Re: Re: [TS-520_820_530_830] RE: New Ham, Tuning issues

You dont need the key or vox or any of the gyrations you are putting your self thru to load your TS830.

The reason Ip indicates approx 60ma when you switch from Tune to CW mode is that you have the plates meshed on the Plate load cap and you are shunting the RF current around the dummy load and circulating it in the Tank.

It is OK to crack the Plate Load control open a little at initial loading so you can see 70 or 80 ma or so if that helps you.

At this point with plates fully meshed you have maximum capacitance and lowest capacitive reactance so the RF current in the tank is going to like to flow thru the plate load cap and not thru the dummy load. Sometime look at formula for Xc and you will see it is an inverse relationship. It will help you understand what I am telling you.

OK --You havent started tightening up the coupling yet and shifting the tank circuit RF circ current to the dummy load resistance. Each time you open the plates of the Load cap a little more you are decreasing the capacitance and increasing the capacitive reactance XC. This allows more current to flow in the dummy load resistor or the antenna.

When you get to full load you will have opened the Plate Load capactor to the point that the XC is approx equal to the dummy load or antenna resistance. At this point you will have used half of the stored energy in the tank and there will be equal RF current flowing thru the Plate load capacitor and the dummy load resistor. At that point with 100 watts output power there will be approx 1.4 RF amps flowing thru the Plate load cap and 1.4 RF amps flowing thru the 50 ohm dummy load.

This is all simple ohms law for parallel resistors, but not too many folks really understand what they are doing or how it works or have just never given it any serious thought.

After you make that initial plate current dip in Tune mode you do not need to do any more dip and load procedure. Only reason you do this initial dip is to get the tank circuit adjusted close to resonance so when you go to CW mode and apply full screen grid voltage to

the finals you dont peg the IP meter if the tank is tuned off resonance. This could damage your finals if left keyed too long at this high Ip level.

Read the very last note in the TS-830 loading procedure. It tells you after they have taught you dip and load you dont have to use it as it isnt best or easiest way to load a Class AB1 linear amp!

It directs you to place meter in RF position and Flip to Send and alternately adjust the plate Load and Tune controls for maximum indicated relative power (RF voltage).

With your wattmeter in line leave your TS830 meter in IP. Now after making that initial plate current dip in Tune mode flip to Send in CW mode and alternately adjust Plate Load and Plate tune controls for approx 100watts output.

Your wattmeter will be far more sensitive to any changes you make than your IP meter. You will quickly be able to find the combination that gives you max rf output power. Take a quick look at IP and it should be close to 225ma. If a little over dont worry about it as 265ma is the real limit.

Lastly, if you are having to increase the Car level at the late stage of tuning you are not setting it high enough in the early Drive control peaking step. There is no reason to have to do this. When you peak the Drive give yourself something to look at. If you peg the ALC meter just reduce the Car level pot to get it off the peg.

I measured R53 yesterday as I thought the same thing. However, it is reading EXACTLY 18k. I redrew that section of the schematic, and it seems like the next culprit would be an open diode or a bad solder connection. If no diode is conducting the current from the voltage divider, the voltage would go high on both sides of R53 since there would be no current flow. That is where the VTVM comes in handy. No perceived drop with 18k. As a matter of fact -- I can measure the voltage of a 9V battery as it passes through both arms with only a 2V drop. That impressed me :D

Having an open diode would also explain the bad audio. I will go pick up some diodes on my lunch break. Not sure if I will have time to replace them after work today. I have a busy evening.

There is no way you can mis- tune the finals and blow a cathode resistor.

I showed the math to you. If it was possible to see 350ma in a mis-tuning event then P = I squared R.

.350 x .350 x 5 = 0.61 watts.

A 2 watt resistor can run dissipating .61 watts forever.

What plate current level do you think could be attained in a mis-tuning event? What happens to the HV power supply voltage at that current level? What is the transformer Secondary power and what is the Primary power at that current level? What happens to the transformer primary fuse?

Even if it was possible to see a 700ma event then .700 x .700 x 5 = 2.45 watts. A 2 watt resistor will run a very very long time dissipating 2.45 watts.

Cathode resistors never blow due to mis-tuning of any kind. They blow most certainly from tube arc over.

Yes not likely bad R53. As I previously noted I have never seen this happen.

I guess should have been more emphatic to look for open ring diodes. After all I think I did the "admonishment" regards the need for a VTVM.

" I do not know why Car Pot is behaving this way. Perhaps you have bad Balanced Modulator ring diodes................."

I like it when the student graduates and flies the nest!

Yes, I think herin lies the problem.

Need to look at Resistor R21 18k close to the CW terminal post. You can use a straight pin. I use 2 inch corsage pins or floral arrangement pins with heat shrink over most of the pin.

These have a pearl ball on the top of them to make handling good. I then clip a mini-grabbber test lead near the head and to the plus lead of my DMM or VTVM test leads. This allows you to probe at the hole where resistor leads enter the component side of the board.

Nice touch with the pins. That is a great tip.

Is measuring across CM and CV equivalent? I did that yesterday and got exactly 18k.

Are you referring to R21 on the GEN board? That is a 10k resistor not directly connected to the modulator bridge. It connects to Q7 on my schematic. Yesterday afternoon I measured R53 to be 18k exactly since it is part of the voltage divider circuit that unbalances the balanced modulator. I don't see a CW terminal that yo referred to, so maybe referring to a board other than the GEN board.

You should find on one side of R21 you have variable voltage from 0 to 9vdc and on the other side from 0 to 0.50vdc. It appears that R21 is shorted which is very unusual. This should be the same voltage at the BM terminal, correct? Is it also possible that one of the BM diodes is open since without a load the voltage divider should go high? I am thinking an open circuit in the BM (one of the diodes not conducting) would have the same effect as R53 shorting. Since the diodes conduct at .25V that would load the 18k resistor and cause a voltage drop across it. If that diode was not conducting the BM side of the 18k resistor would go high -- especially since I am measuring 18k across that resistor.

You will have to fold the Gen Board over to replace R21 so at that time I would also check the balanced modulator diodes D1, D2, D3, D4 given you have reported distorted audio.

My guess is that one of the diodes that is supposed to conduct to unbalance the modulator either has a bad solder joint or has gone open. However, I am going to defer to you on this since you have far more experience with this radio.

Since! you have to lift one lead of each diode to check them I would just go ahead and replace all 4 of them. Do not use Silicon switchers like 1N914 diodes. 1n60s and 1n270s are fine. Mouser will have and Scotts Electronics who sells Crystal radio parts is a good supplier of the germanium signal diodes.

I have an old school electronics store one town over so I think I am going to stop in and check to see if they have them.

I am exactly sure what you are asking. If you are asking about how to load a TS520 that has no Tune Ip indication to get that initial plate current dip and is it different than a TS-830 then answer is no difference other than limiting the plate current to 200ma.

Some people with lots of experience load in CW mode. Some do this as they have a good understanding of what is going on and the pre-cautions using this method.

Others do it because the Tune position of their rig quit years ago and too lazy to fix it or dont know how to fix it.

I typically do not teach new folks to load in CW.

However if your rigs Tune position is out and you cannot get that initial plate current dip then you can do it by reducing the Car Level pot to minimum and with meter in Ip position Flip to Send and slowly bring the Car Level up to something under 100ma. Have to be careful because Ip can jump very high pretty quickly with very little more opening of the pot.

When you get say around 80ma to 100ma then adjust the plate Tune capacitor for a dip or minimum in plate current and then unkey the rig. Now ready to use the RF relative power position of the panel meter or your external wattmeter to start coupling load. Flip to Send and alternately adjust Plate Load and Plate Tune controls for max relative power on your RF meter position or approx 100 watts output on your wattmeter. Unkey the rig.

Watching the Ip meter flip to send again and if you are reasonably close to 200ma Ip you are done and ready to operate CW or SSB.

WIth a good Tune position I recommend you follow the instructions in your TS520 manual. Only confusing step is peaking the Drive which says to adjust for maximum meter deflection and everyone and I mean everyone asks "what maximum"? The ALC black box maximum or the meter full scale maximum. As I think I told you black box is meaningless at this step but OK to just peak Drive control at max range on it.

After you get that initial plate current dip in Tune mode then all the Kenwood instruction manuals direct you to load by alternately adjusting :Load and Tune controls for max RF relative power. If you have an external wattmeter leave meter in Ip and load for approx 100 watts out without exceeding 200ma.

Subject: RE: Re: [TS-520_820_530_830] New Ham, Tuning issues

Brian:

No problem with using a Key to load the rig. Just not necessary when bench testing a rig. The 830 manual contributes to this when early on they tell you to connect dummy load or antenna and connect a Key and then flip to Send and check resting plate current. However they fail to tell you to press the Key or close the slider if a straight Key. Later under Transmission section under CW header they tell you again to install a Key. Poorly written.

When you turn the Plate Load cap control CW off the full CCW position and you see the RF output power on the wattmeter go down do you then immediately adjust the Plate Tune capacitor to try to bring the RF output power back up?

Anytime the Load cap is moved open or closed you need to make a slight adjustment with the Tune capacitor to restore the tank to resonance. What happens when you do this?

Typically once the reactance of the Plate Load capacitor is close to the impedance of the load (antenna or dummy load) opening the plates (CW) any more usually does not result in anymore RF output on the wattmeter. You reach a point where opening the plates more does not result in coupling any more load. The final tubes just cannot supply any more RF Line current to the Tank.

There is no doubt that loading on 40 meters into a 50 ohm dummy load you should not be at maximum RF output with the Plate Load cap full CCW (plates fully meshed). As you suggest it is not "normal". You know that from your own TS-830.

As I mentioned this is indicative of bad fixed padder caps that are switched in on the lower bands. The reason that this is necessary is if they installed an air variable capacitor that had the necessary high level of capacitance on the lower bands it would then

have a minimum capacitance with the plates completely open that would be far too high to function on higher bands. 10 meters is the biggest challenge for the designers. Same for the Plate Tune capacitor.

If you get time it would be good to see if it loads normal on 15 and 10 meters. I would try loading on all the bands and make a chart of how it behaves. Where does the plate Load cap end up for approx 100 watts output at 200ma Ip.

One other thing you should look at if comfortable is the main RF plate choke and the small VHF choke at a right angle at its base and the rf bypass cap at its base. If these show signs of overheating then will need to be replaced. The by pass cap can actually physically split the case open.

Need to have rig unplugged and let set for awhile to led bleeders discharge the HV filter caps. Then remove PA cage cover. Then connect ground jumper from top of plate choke and ground for a few seconds. Now safe to use a good flashlite and inspect these items.

I would also look at both capacitor shaft couplers at the PA cage and make sure screws are tight. Can also watch the travel and make sure full open and full close align with markings on the front panel.

Hi Terry:

Ah ha. I am a CW op so I always have had a key plugged in (but no mic). Anyway, with a key plugged in you don't get any output with the alternate procedure without closing the key for obvious reasons. I've been so used to how the radio responded when I switched over from tune to CW with a key connected that I ended up thinking the key was necessary. My bad. For me the long procedure from the manual works fine since I always have the key connected and normally have the radio in VOX mode (to save wear on the send switch) but I have a better understanding now. Thank you. I will also study the diagram to try to better understand the relationship between the load capacitor and antenna load.

This will also help Jason since I took him through the long procedure from the manual that uses a key. He can just unplug his keyer and will be able to move from tuning to loading once he has the drive and plate a resonance (peaked and dipped) without all of the additional gyrations.

Questions: This still leaves Jason's TS-520's issue with load. Even though I was using the long procedure with the key, I think the results are still accurate. He is getting a maximum output of 70w at 200ma with the load at min (fully CCW) and reducing the load capacitance (increasing the load/turning load CW) actually reduces his output. This isn't normal, right? I can simulate this on my TS-830 but it pains me. If I intentionally turn the load up too much, output falls off as I increase the load. So...I think in Jason's TS520 it is as if even at maximum capacitance (minimum load) he doesn't have enough to balance against the 50 ohm dummy load---resonance is off the minimum end of the load. Does that sound like a reasonable conclusion? Is the next step for us to try the tune up procedure on all bands and report back (your 10m suggestion from before) or is there something else that we should check first?

Thanks,
Brian (and Jason)

Subject: RE: Re: Re: [TS-520_820_530_830] RE: New Ham, Tuning issues

You dont need the key or vox or any of the gyrations you are putting your self thru to load your TS830.

The reason Ip indicates approx 60ma when you switch from Tune to CW mode is that you have the plates meshed on the Plate load cap and you are shunting the RF current around the dummy load and circulating it in the Tank.

It is OK to crack the Plate Load control open a little at initial loading so you can see 70 or 80 ma or so if that helps you.

At this point with plates fully meshed you have maximum capacitance and lowest capacitive reactance so the RF current in the tank is going to like to flow thru the plate load cap and not thru the dummy load. Sometime look at formula for Xc and you will see it is an inverse relationship. It will help you understand what I am telling you.

OK --You havent started tightening up the coupling yet and shifting the tank circuit RF circ current to the dummy load resistance. Each time you open the plates of the Load cap a little more you are decreasing the capacitance and increasing the capacitive reactance XC. This allows more current to flow in the dummy load resistor or the antenna.

When you get to full load you will have opened the Plate Load capactor to the point that the XC is approx equal to the dummy load or antenna resistance. At this point you will have used half of the stored energy in the tank and there will be equal RF current flowing thru the Plate load capacitor and the dummy load resistor. At that point with 100 watts output power there will be approx 1.4 RF amps flowing thru the Plate load cap and 1.4 RF amps flowing thru the 50 ohm dummy load.

This is all simple ohms law for parallel resistors, but not too many folks really understand what they are doing or how it works or have just never given it any serious thought.

After you make that initial plate current dip in Tune mode you do not need to do any more dip and load procedure. Only reason you do this initial dip is to get the tank circuit adjusted close to resonance so when you go to CW mode and apply full screen grid voltage to the finals you dont peg the IP meter if the tank is tuned off resonance. This could damage your finals if left keyed too long at this high Ip level.

Read the very last note in the TS-830 loading procedure. It tells you after they have taught you dip and load you dont have to use it as it isnt best or easiest way to load a Class AB1 linear amp!

It directs you to place meter in RF position and Flip to Send and alternately adjust the plate Load and Tune controls for maximum indicated relative power (RF voltage).

With your wattmeter in line leave your TS830 meter in IP. Now after making that initial plate current dip in Tune mode flip to Send in CW mode and alternately adjust Plate Load

and Plate tune controls for approx 100watts output.

Your wattmeter will be far more sensitive to any changes you make than your IP meter. You will quickly be able to find the combination that gives you max rf output power. Take a quick look at IP and it should be close to 225ma. If a little over dont worry about it as 265ma is the real limit.

Lastly, if you are having to increase the Car level at the late stage of tuning you are not setting it high enough in the early Drive control peaking step. There is no reason to have to do this. When you peak the Drive give yourself something to look at. If you peg the ALC meter just reduce the Car level pot to get it off the peg.

I am glad you have a good attitude about this. I have had some arrogant elmers in the past that would get all pissy when I questioned their reasoning. I don't have a ton of electronics experience, but I am a physics instructor. This means I have a lot of practice breaking down and analyzing problems. I try to be as gentle at presenting my disagreements, but I have learned that I do need to speak up to avoid going down the rabbit hole fixing things that are not broken. :D

Also, do the diodes need to match since it is a balanced bridge type of circuit? I notice VR1 should cancel some differences, but maybe not all of the diode properties. I bought four Ge diodes (1n60 equivalent) just in case, but I am a cheap skate and would like to take back what I don't use. I imagine I will have to balance the modulator again to get rid of any carrier, or would these be close enough to still balance? I hope at some point to have a working radio. I do really like its looks and receiver. My only gripe is that the dial spins backwards compared to any other rig I have used.

I am wondering if this radio died very early on in its career because it is a very pristine example of a TS-520S.

What type of probe did you use to calibrate DC? If you used a straight through probe, without a 1meg resistor in series with the probe's tip, then the DC calibration will be wrong.

The 1 meg resistor is not required for ohms and AC volts so you can calibrate AC with a straight through probe.

I think you will enjoy the VTVM, especially once you get use to the scales. It will give you years of service.

I was referring to checking and replacing the padder caps and the other items you described the other day. Brain was helping me tune my TS-520 and the discussion was about complications with that. You mentioned in a couple of previous posts that you were talking about a TS-830. I was concerned there was some confusion about what model of Kenwood was experiencing the issues described in this thread. If they all work the same, I'll get those padder caps tested and look at the other items referred to in your previous post.

I hope that's not more confusing, hehe. Brian knows better than I do and was able to explain the problems better than I could.

OK sorry for the confusion. I am clearly confused on who I am taking to at this point and what the problem is. I dont think we discussed yet how to measure/test the fixed padder caps in any rig. I think we last left off with asking you to load test your rig on each band and not just 40 and 20 meters and reporting back the results?

However if your rigs Tune position is out and you cannot get that initial plate current dip then you can do it by reducing the Car Level pot to minimum and with meter in Ip position Flip to Send and slowly bring the Car Level up to something under 100ma. Have to be careful because Ip can jump very high pretty quickly with very little more opening of the pot.

When you get say around 80ma to 100ma then adjust the plate Tune capacitor for a dip or minimum in plate current and then unkey the rig. Now ready to use the RF relative power position of the panel meter or your external wattmeter to start coupling load. Flip to Send and alternately adjust Plate Load and Plate Tune controls for max relative power on your RF meter position or approx 100 watts output on your wattmeter. Unkey the rig.

Watching the Ip meter flip to send again and if you are reasonably close to 200ma Ip you are done and ready to operate CW or SSB.

WIth a good Tune position I recommend you follow the instructions in your TS520 manual. Only confusing step is peaking the Drive which says to adjust for maximum meter deflection and everyone and I mean everyone asks "what maximum"? The ALC black box maximum or the meter full scale maximum. As I think I told you black box is meaningless at this step but OK to just peak Drive control at max range on it.

After you get that initial plate current dip in Tune mode then all the Kenwood instruction manuals direct you to load by alternately adjusting :Load and Tune controls for max RF relative power. If you have an external wattmeter leave meter in Ip and load for approx 100 watts out without exceeding 200ma.

Subject: RE: Re: [TS-520_820_530_830] New Ham, Tuning issues

Brian:

No problem with using a Key to load the rig. Just not necessary when bench testing a rig. The 830 manual contributes to this when early on they tell you to connect dummy load or antenna and connect a Key and then flip to Send and check resting plate current. However

they fail to tell you to press the Key or close the slider if a straight Key. Later under Transmission section under CW header they tell you again to install a Key. Poorly written.

When you turn the Plate Load cap control CW off the full CCW position and you see the RF output power on the wattmeter go down do you then immediately adjust the Plate Tune capacitor to try to bring the RF output power back up?

Anytime the Load cap is moved open or closed you need to make a slight adjustment with the Tune capacitor to restore the tank to resonance. What happens when you do this?

Typically once the reactance of the Plate Load capacitor is close to the impedance of the load (antenna or dummy load) opening the plates (CW) any more usually does not result in anymore RF output on the wattmeter. You reach a point where opening the plates more does not result in coupling any more load. The final tubes just cannot supply any more RF Line current to the Tank.

There is no doubt that loading on 40 meters into a 50 ohm dummy load you should not be at maximum RF output with the Plate Load cap full CCW (plates fully meshed). As you suggest it is not "normal". You know that from your own TS-830.

As I mentioned this is indicative of bad fixed padder caps that are switched in on the lower bands. The reason that this is necessary is if they installed an air variable capacitor that had the necessary high level of capacitance on the lower bands it would then have a minimum capacitance with the plates completely open that would be far too high to function on higher bands. 10 meters is the biggest challenge for the designers. Same for the Plate Tune capacitor.

If you get time it would be good to see if it loads normal on 15 and 10 meters. I would try loading on all the bands and make a chart of how it behaves. Where does the plate Load cap end up for approx 100 watts output at 200ma Ip.

One other thing you should look at if comfortable is the main RF plate choke and the small VHF choke at a right angle at its base and the rf bypass cap at its base. If these show signs of overheating then will need to be replaced. The by pass cap can actually physically split the case open.

Need to have rig unplugged and let set for awhile to led bleeders discharge the HV filter caps. Then remove PA cage cover. Then connect ground jumper from top of plate choke and ground for a few seconds. Now safe to use a good flashlite and inspect these items.

I would also look at both capacitor shaft couplers at the PA cage and make sure screws are tight. Can also watch the travel and make sure full open and full close align with markings on the front panel.

Hi Terry:

Ah ha. I am a CW op so I always have had a key plugged in (but no mic). Anyway, with a key plugged in you don't get any output with the alternate procedure without closing the key for obvious reasons. I've been so used to how the radio responded when I switched over from tune to CW with a key connected that I ended up thinking the key was necessary. My bad. For

me the long procedure from the manual works fine since I always have the key connected and normally have the radio in VOX mode (to save wear on the send switch) but I have a better understanding now. Thank you. I will also study the diagram to try to better understand the relationship between the load capacitor and antenna load.

This will also help Jason since I took him through the long procedure from the manual that uses a key. He can just unplug his keyer and will be able to move from tuning to loading once he has the drive and plate a resonance (peaked and dipped) without all of the additional gyrations.

Questions: This still leaves Jason's TS-520's issue with load. Even though I was using the long procedure with the key, I think the results are still accurate. He is getting a maximum output of 70w at 200ma with the load at min (fully CCW) and reducing the load capacitance (increasing the load/turning load CW) actually reduces his output. This isn't normal, right? I can simulate this on my TS-830 but it pains me. If I intentionally turn the load up too much, output falls off as I increase the load. So...I think in Jason's TS520 it is as if even at maximum capacitance (minimum load) he doesn't have enough to balance against the 50 ohm dummy load---resonance is off the minimum end of the load. Does that sound like a reasonable conclusion? Is the next step for us to try the tune up procedure on all bands and report back (your 10m suggestion from before) or is there something else that we should check first?

Thanks,
Brian (and Jason)

Subject: RE: Re: Re: [TS-520_820_530_830] RE: New Ham, Tuning issues

You dont need the key or vox or any of the gyrations you are putting your self thru to load your TS830.

The reason Ip indicates approx 60ma when you switch from Tune to CW mode is that you have the plates meshed on the Plate load cap and you are shunting the RF current around the dummy load and circulating it in the Tank.

It is OK to crack the Plate Load control open a little at initial loading so you can see 70 or 80 ma or so if that helps you.

At this point with plates fully meshed you have maximum capacitance and lowest capacitive reactance so the RF current in the tank is going to like to flow thru the plate load cap and not thru the dummy load. Sometime look at formula for Xc and you will see it is an inverse relationship. It will help you understand what I am telling you.

OK --You havent started tightening up the coupling yet and shifting the tank circuit RF circ current to the dummy load resistance. Each time you open the plates of the Load cap a little more you are decreasing the capacitance and increasing the capacitive reactance XC. This allows more current to flow in the dummy load resistor or the antenna.

When you get to full load you will have opened the Plate Load capactor to the point that the XC is approx equal to the dummy load or antenna resistance. At this point you will have used half of the stored energy in the tank and there will be equal RF current flowing thru the Plate load capacitor and the dummy load resistor. At that point with 100 watts output

power there will be approx 1.4 RF amps flowing thru the Plate load cap and 1.4 RF amps flowing thru the 50 ohm dummy load.

This is all simple ohms law for parallel resistors, but not too many folks really understand what they are doing or how it works or have just never given it any serious thought.

After you make that initial plate current dip in Tune mode you do not need to do any more dip and load procedure. Only reason you do this initial dip is to get the tank circuit adjusted close to resonance so when you go to CW mode and apply full screen grid voltage to the finals you dont peg the IP meter if the tank is tuned off resonance. This could damage your finals if left keyed too long at this high Ip level.

Read the very last note in the TS-830 loading procedure. It tells you after they have taught you dip and load you dont have to use it as it isnt best or easiest way to load a Class AB1 linear amp!

It directs you to place meter in RF position and Flip to Send and alternately adjust the plate Load and Tune controls for maximum indicated relative power (RF voltage).

With your wattmeter in line leave your TS830 meter in IP. Now after making that initial plate current dip in Tune mode flip to Send in CW mode and alternately adjust Plate Load and Plate tune controls for approx 100watts output.

Your wattmeter will be far more sensitive to any changes you make than your IP meter. You will quickly be able to find the combination that gives you max rf output power. Take a quick look at IP and it should be close to 225ma. If a little over dont worry about it as 265ma is the real limit.

Lastly, if you are having to increase the Car level at the late stage of tuning you are not setting it high enough in the early Drive control peaking step. There is no reason to have to do this. When you peak the Drive give yourself something to look at. If you peg the ALC meter just reduce the Car level pot to get it off the peg.

If I mis-speak or am flat wrong I want people to speak up. Worse thing we can do is bum-dope anyone and they run with that info. I am performing a juggling act here and can get in trouble relying mostly on memory and my notes (which frankly are not very well organized).

I am also pretty astute at telling who the people are who think they have all the answers and pretty quickly move on as they surely dont need anything this old man has to offer.

A purist would say yes you need to use a matched set both for the Balanced Mod and the Product detector, but in practice not likely you will notice the difference.

Also, today they would use Schottky (hot carrier) diodes. Some on the forum have installed them and report improved performance, but suspect much of this is anecdotal and not based on before and after measurements. Cant hurt to try them, but if you are frugal then the germaniums will be cheaper. 1N5711 was the diode of choice in recent past. .

May be able to match your diodes using the Diode test position of your DMM, but better way is to use regulated power supply or battery and build a test circuit.

1. Place diode under test in series with around 4.7k resistor.
2. Connect regulated 9vdc or 12vdc power supply across the series combo (absent bench power supply could use the 9vdc from your rigs AVR board or fresh 6 volt lantern batteries)
3. Place DMM leads across the diode.and place on 2vdc range
4/ Let the diode warm up maybe 30 seconds.
5. Read and record the voltage to 3 decimal places.

Remove diode and place another in series and repeat. Select 4 diodes that have as close to same recorded voltage as you can.

4.7k @ 9vdc = 2ma of current flowing thru the forward biased diode.
4,7k @ 12vdc = 2.5ma current

Problem with many DMM diode test positions is that they dont push much current. As a Physics major you will have studied the barrier voltage and temperature effect.

I like it when the student graduates and flies the nest!

I am glad you have a good attitude about this. I have had some arrogant elmers in the past that would get all pissy when I questioned their reasoning. I don't have a ton of electronics experience, but I am a physics instructor. This means I have a lot of practice breaking down and analyzing problems. I try to be as gentle at presenting my disagreements, but I have learned that I do need to speak up to avoid going down the rabbit hole fixing

things that are not broken. :D

Also, do the diodes need to match since it is a balanced bridge type of circuit? I notice VR1 should cancel some differences, but maybe not all of the diode properties. I bought four Ge diodes (1n60 equivalent) just in case, but I am a cheap skate and would like to take back what I don't use. I imagine I will have to balance the modulator again to get rid of any carrier, or would these be close enough to still balance? I hope at some point to have a working radio. I do really like its looks and receiver. My only gripe is that the dial spins backwards compared to any other rig I have used.

I am wondering if this radio died very early on in its career because it is a very pristine example of a TS-520S.

I was referring to checking and replacing the padder caps and the other items you described the other day. Brain was helping me tune my TS-520 and the discussion was about complications with that. You mentioned in a couple of previous posts that you were talking about a TS-830. I was concerned there was some confusion about what model of Kenwood was experiencing the issues described in this thread. If they all work the same, I'll get those padder caps tested and look at the other items referred to in your previous post.

I hope that's not more confusing, hehe. Brian knows better than I do and was able to explain the problems better than I could.

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

I am exactly sure what you are asking. If you are asking about how to load a TS520 that has no Tune Ip indication to get that initial plate current dip and is it different than a TS-830 then answer is no difference other than limiting the plate current to 200ma.

Some people with lots of experience load in CW mode. Some do this as they have a good understanding of what is going on and the pre-cautions using this method.

Others do it because the Tune position of their rig quit years ago and too lazy to fix it or dont know how to fix it.

I typically do not teach new folks to load in CW.

However if your rigs Tune position is out and you cannot get that initial plate current dip then you can do it by reducing the Car Level pot to minimum and with meter in Ip position Flip to Send and slowly bring the Car Level up to something under 100ma. Have to be careful because Ip can jump very high pretty quickly with very little more opening of the pot.

When you get say around 80ma to 100ma then adjust the plate Tune capacitor for a dip or minimum in plate current and then unkey the rig. Now ready to use the RF relative power position of the panel meter or your external wattmeter to start coupling load. Flip to Send

and alternately adjust Plate Load and Plate Tune controls for max relative power on your RF meter position or approx 100 watts output on your wattmeter. Unkey the rig.

Watching the Ip meter flip to send again and if you are reasonably close to 200ma Ip you are done and ready to operate CW or SSB.

WIth a good Tune position I recommend you follow the instructions in your TS520 manual. Only confusing step is peaking the Drive which says to adjust for maximum meter deflection and everyone and I mean everyone asks "what maximum"? The ALC black box maximum or the meter full scale maximum. As I think I told you black box is meaningless at this step but OK to just peak Drive control at max range on it.

After you get that initial plate current dip in Tune mode then all the Kenwood instruction manuals direct you to load by alternately adjusting :Load and Tune controls for max RF relative power. If you have an external wattmeter leave meter in Ip and load for approx 100 watts out without exceeding 200ma.

I was kind of figuring this was one of "those" sorts of disagreements. His is the only place for that particular bit of 'information' that is of any size or popularity.

I will take it under advisement. In the mean time I will try using same-size / same type parts as often as possible.

I have even found a London-based source for the V06B diodes, and I am going to order a few. (Looks like thirty at least, from the people who have contacted me to get added to the order. Need any? Going to cost me about a quarter each. My price = your price, to within a penny or so. Rounding errors. No risk, no cost, until they arrive. And if you stiff me (as if!) I've learned more than that much from your posts to the list.)

But I'm not going to wait a month or six weeks to get those diodes. Local-procured, I've got a friend in the radio repair business, mostly puts radios and radars in squad cars for the area PDs and Sheriffs departments) who likely has four diodes in his parts bin.

Now, a question, or a request for a quick measurement would be more like it. Humour me here, please.

I am very chary of powering this 520SE back on if there is a short somewhere in the system. It failed when I had plugged in the DG-5 freq counter. Flipped the switch and smelled silicon burning. It actually burned off two traces on the underside of the board, one on each side of

the diode bridge. AND ate the diodes, they were brown and shattered when I touched them to desolder. I've repaired the traces with wire and solder.

But the counter, when powered from my bench supply, seems to be working fine, used as a frequency meter with my old Eico generator as a signal source.

The request is for a simple resistance measurement across the 12V power socket where you would plug in that freq counter. Positive side to chassis ground. I get 60 ohms, slowly rising as a capacitor (obviously) charges through. Starts at 58.8 on the digital meter, the ~60% charge happens in about three seconds, and it continues, slowing of course, to just over 60.3 ohms. After that it takes most of a minute to get to 60.4.

Is that the typical resistance there, power off and just sitting? I know it's a meaningless measurement for most purposes, but I was looking for a short or close to it on that line, and it seems quite a bit low. If that were the actual live circuit resistance, that's nearly 5 amps (E/R, R being assumed to be around 14 VDC).

Oh, and one other thing. Is there ANYWHERE, in any format, documentation for the colour code used in this thing? Besides the missing side-tone bias line on an identically-numbered board (that's shoddy engineering management in my opinion - change the board, change the number), the colour scheme on the the replacement board was totally different with the exception of a few (mostly the red, black, and green) wires. Fully half of the connections were to white-with-coloured-stripe wires, which were totally absent on the replacement part.

I'm annotating my working copy of the schematic, and the copies of the circuit board layout drawings, with the colours as I touch things, but that's going to take a LONG time to complete. And I am not a fan of recreating wheels, so if that information already exists somewhere I would sure appreciate knowing about it.

Thanks for taking the time for the email. It's appreciated. And by the way, one sure sign of "guru-hood" is saying you're not one in the face of convincing evidence to the contrary, Sensei.

Yaaaaay! Best feeling in the world. It works!

1. 100W out on CW and solid SSB peaks.

2. Great punchy and clean audio.

3. The CAR control now works in the correct direction.

Some tidying up to do:

1. I only replaced two of the four diodes. The bad one was actually physically broken. It fell apart as I took it out. I noticed there was a very thin piece of wire that had fallen from somewhere across the trace by the diodes -- maybe this killed the diode. I am debating replacing the other two for a matched set. However, I am strongly tempted to leave well enough alone.

2. I now need to rebalance the modulator -- there is carrier present. However, I figured as much.

Thanks for all of the help!

That is great. You will never forget this one if ever see it again.

I think I would just null the carrier and operate as is for now.

Have fun.

The carrier is not nulling out with VR2 and TC1. I am thinking the other two diodes need to be replaced for the circuit to balance. They have a slightly different forward voltage drop than the new Ge diodes. What do you think?

Looks like the relay was not the problem - the Function switch is the trouble. I twisted the Function switch several times while the VFO was powered on, and I found out letting the switch seat normally it would not work.

It does work, though, by ALMOST letting it seat but resting on the notch just before seating properly. It's not easy to let the switch sit on that edge, but it works that way on all 4 points of the switch.

I cleaned the switch before with DeOxit so it should be clean.

Any ideas? Does the switch have to be replaced?

NOT being the Kenwood guru, but having built home-brew and kits back in the 70's and 80's, and having a bunch of papers on the wall (well, in a box, I'm not a 'wall' kind of person) saying I'm supposed to know something about this stuff,

YES, match the diodes. The old ones will be rather different than the new ones. If you had one of each old and new in each side of the ring, it might balance. But since I suspect the new ones are on one half, the old ones on the other, you are going to have a 'lop-sided' frequency response.

If making all four equivalent doesn't fix the problem, I will be rather amazed. And it cannot hurt to make them equivalent types.

(Besides, I've found those glass diodes to be much too fragile all around for my tastes. Physically. Just desoldering them can break the package.)

If nobody else has better information then from what I know and what I see in the schematic, they need to be close (not exactly matched) to the same values for it to balance and null properly. (Come on, gurus, if I'm wrong, please say so. I do NOT mind being told I'm wrong. It's how I learn.)

You were definitely 100% on point. I replaced all four and she is 100%
operational. I am getting good audio reports and CW RSTs. I was able to
balance the modulator with no carrier. Full power out, and the CAR is
behaving the way it should.

Thanks,
Chris Maness KQ6UP

44641. TS511 Question

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-17 04:24:33 UTC

Topic: 44641 Message: 44641

While the 511 is not a 20 or 820 it is a Kenwood Hybrid and I am hoping someone knows the answer to this question... I have a 511 and have a 500 hz filter from a 520 and my understanding is that it should work fine in a TS511...So the question is does any one have instructions for installing the filter into a TS511, the manual is silent on installation. The 520 requires you to move a jumper. I can not find any service manual that address this either. I beleive you must also change one of the carrier oscillator crystals but am not sure. The manual talks about a different carrier freq when you have a CW filter installed as opposed to when you do not. It does not say you have to change the crystal..Any information about this is appreciated. I think you have to change the crystal from 3395.0 to 3394.3. The 3395.0 is the I have in the radio.

Thanks Steve

I'm looking at my rig, and I would like an opinion on this from them
what knows.

Could it be a problem with the pressure of the copper contact 'fingers'
on the wafers of the band switch? Can they sort of relax over time and
not make firm connection any more?

If this is a possibility, is it not possible, therefore, to take a probe
or something blunt (fingers? fingernail?) and gently bend them in tight
against the wafer again?

Would that be a possible fix, and could that be the base problem here?

It might also be corrosion on the spot the finger has been "seating" all
these years, or even may be the copper there is worn off or almost off.
If that is the case, can it be repaired with something like
silver-bearing trace paint? I doubt this, highly, but if it would work
it might save a LOT of tedious work replacing a band switch.

Might make better connections to the wires leading OFF of the switch,
those rivet dealy-bobs look like a failure point waiting to happen to
me. I think solder there would be better than silver paint, if done
VERY carefully. Wouldn't want to damage the foil traces on the wafers
with too much heat.

Or is this a "new bandswitch" fix only??

Enlightenment, anyone?

LOLOL Yes, a lack of smoke and sparks when you flip the switch, and a working gadget in front of you where it wasn't before, it's a good feeling.

When I got the 520SE to work the other day (before the freq counter took it back down), I let out a whoop that startled my dogs, and brought SWMBO out of her homework-grading trance. She laughed at me, doing a little dance around the workbench....

And laughed at me some more when all the lights went back out about half an hour later.

(I thought that was rather mean of her, but I suspect the crest-fallen look on my face as the little wisp of smoke from the toasted diodes and that bit of foil on the circuit board rose into the air, well, it must have been rather amusing to see.)

Enjoy the radio. You've earned the right to that feeling.

Wes,

He is saying "function switch", not bandswitch. The bandswitch could be
a coupler off just a bit, but I'm not sure about the function switch. I
too am curious as to thoughts.

Remember depending on the radio that you have four 1/2 watt or two 1 watt in parallel for 2 watts dissipation.

Terrry,
The cathode resistors are only 1/2 watt aren't they ?

On 9/16/2013 11:25 AM, wagstw46@... wrote:

There is no way you can mis- tune the finals and blow a cathode resistor.

I showed the math to you. If it was possible to see 350ma in a mis-tuning event then P = I squared R.

.350 x .350 x 5 = 0.61 watts.

A 2 watt resistor can run dissipating .61 watts forever.

What plate current level do you think could be attained in a mis-tuning event? What happens to the HV power supply voltage at that current level? What is the transformer Secondary power and what is the Primary power at that current level? What happens to the transformer primary fuse?

Even if it was possible to see a 700ma event then .700 x .700 x 5 = 2.45 watts. A 2 watt resistor will run a very very long time dissipating 2.45 watts.

Cathode resistors never blow due to mis-tuning of any kind. They blow most certainly from tube arc over.

Yes - the Function switch on the external VFO is the culprit. It works when sitting on the edge as I mentioned, but it doesn't work when it seats completely where it's supposed to.

Any ideas from anyone?

Good morning,

I uploaded a new video to my folder on Gordon's webserver. The following link will take you to the video:

http://www.n6wk.com/w5rkl/Grid%20Voltage/Grid%20voltage%20changes%20based%20on%20sine%20wave%20voltage%20levels.wmv

This video briefly explains a sine wave, what a sine wave looks like, the positive half and the negative half segment of the sine wave, and the different degrees throughout the sine wave cycle.

The video also shows/discusses what the terms "Peak Voltage" AND "Peak to Peak" voltages are when referenced to a sine wave cycle and what each term means. These are terms that you need to know and what they mean so you will understand what a discussion is about when the terms are used.

The remainder of the video discusses how the GRID voltage changes based on the sine wave cycle voltages that occur throughout the sine wave cycle.The video also explains that the GRID BIAS voltage applied to the grid, -4 volts in the example shown in the video, DOES NOT CHANGE throughout the entire applied signal's sine wave cycle!!! This is important to fully understand!!

Go to ebay and search on 3 pole 4 position (3P4T) rotory switches (non-shorting).

Should find a lot of phenolic, ceramic and enclose styles at low prices.

The funny thing is I purchased an FT-107M to have a great sounding vintage rig. I had gave up on the TS-520s way back in 2009 according to the old threads in this group. Since I purchased the, 107 I decided to sell the old TS-520S. I brought in the shack to jog my memory as to what was wrong with it so that I could list the problem in the add. I instantly fell in love again with the receiver audio. The only option was a renewed effort to fix the old gal. Looking at the old thread I had previously noted how nice the radio was, and saw that I had resolved other alignment related issues. The ironic thing is that the thread is titled almost exactly the same as this one, and their is a fair degree of wild goose chasing in that thread too hi hi.

Yes,
I knew that, but I was talking about "Resistor" as you, when you
said 2 watt resistor.
I wouldn't want some one to put in two or four "2 Watt" resistors.
Just keeping the info clear.

Excellent presentation Mike. Thanks for the great refresher course. I'm from the tube days but spent most or my career in the solid state arena before retirement. I look forward to your future presentations. I'm sure the hams that are interested in learning all about the Hybrids appreciate you spending your time providing this education . What's interesting, especially to the new people, is that we need only learn about three tubes. The driver tube and two output tubes. Again great job!

73,
Ken - KI5PM

Itappears, based on your comments, the problem is not dirty switch wafer contacts but rather the problem could quite possibly be a "mechanical" problem with the switch assembly.

I would look at the "mechanics" of the switch.Don't just look at the switch's mounting, look closer at the switch wafer while rotating the switch knob/shaft very slow. Use a magnifying glass if you have to. I've found AND fixed many "mechanical" problems with switch wafers by simply taking some time, look very close at the switch through a magnifying glass, and rotating the switch shaft very slow. Not all mechanical issues with switch wafers can be fixed. I had a multi-position switch on my DX-40 that had a "mechanical" problem that effected the TUNE position, the switch was damaged after close inspection with a magnifying glass. I had to replace the switchbut I could easily see the mechanical damage that occurred with the switch using a magnifying glass that I could NOT see with the naked eye.

Most of the Motorola mics are low Z and must have a bias voltage on them from the mic High line in the radio to run the mic/s internal.amp circuit. !
 Sorry no go with the Kenwood Hybrids !

Most of the commercial Motorola mics are low Z and require a DC bias voltage supplied by the radio on the mic hi line for the internal amp circuit to work.
. Sorry no match to the Kenwood hybrids.

I used the Shure 404C. It is high impedance and a good match for either rig.

Thank you Ken, you're welcome. I enjoy making the videos.

While the video used a Pentode as the subject tube, the exact same variations in sine wave voltages that are added to the fixed bias voltage resulting in variation in "grid voltage" also applies to the Kenwood Hybrid driver and final tubes!The driver and final tubes operate the same way.

I decided to make it a 2 part video so I renamed that video as:

"Grid voltage changes based on sine wave voltage levels part 1.wmv".

I am working on "part 2" which will expand on part 1, showing how variations in grid voltage causes variations in plate and screencurrent and voltagewhich is basically how a vacuum tube amplifies.

Backto the video production.

Again, thank you for your support and I'm glad thevideos served as a refresher for you. Hopefully they will help those who want to learn how a vacuum tube works.

I can't say whether it's going to be easy for you or not.Only you can
answer that question. I also don't have a VFO-820 to even look closely
at the switch assemblyto tell whether it's going to be easy or
difficultto replace.

Mike:

You are in the same boat I am in. Very unusual for a remote VFO selector switch to be bad as these things get about 10% of the cycles of the rigs switches. Could be an easy mechanical fix. I have no idea of physical size or if it is a hermetically sealed type. Just wanted him to know that he might be able to find a sub on ebay.

If it was on my bench here would look at it and see if can be adjusted. If a phenolic wafer with ball bearing detent and riveted construction probably not. But first need to look at it and then you have an idea as to size etc. I have had a 820 remote here in past but could not tell you what the switch looks like.

Attempt fix 1st and then find a sub. I checked Kenwood East and West and listed as discontinued.

Terry K9TW

I can't say whether it's going to be easy for you or not. Only you can answer that question. I also don't have a VFO-820 to even look closely at the switch assembly to tell whether it's going to be easy or difficult to replace.

Mike

On 9/17/2013 12:44 PM, Barry wrote:

Yeah, I bet you're right. Hopefully it won't be a hard thing to fix for me, but I'm going to take Terry's advice and buy one of these:

http://www.ebay.com/itm/1x-Rotary-Switch-3-Pole-4-Position-3P4T-Non-Shorting-4P-/270743901923?pt=LH_DefaultDomain_0&hash=item3f099816e3

For $3.45 I'm sure it'll be worth it. Is it hard to do the replacement?

Topic: 44437 Message: 44665

I had a problem with the VFO-820 Function switch when I had my TS-820/VFO-820 a few years ago. The problem turned out to be a very dirty wafer switch. Once I cleaned it, everything was fine.

I just looked at the VFO-820 schematic and the Function switch has 3 sections, each having 4 non-shortingpositions. Having done that I still can't say if the eBay replacement switch will work. I don't know how big the VFO-820 switch is nor the size and depth of the eBay switch. I also don't know the eBay switch's terminal mapping. The seller does not say if he includes a schematic diagram of the switch so Barry would have to make his own using an Ohm meter.

The important thing if Barry buys the switch, is for Barry to "map" out the switch contacts using an Ohm meter so he would know which is the wiper on all 3 sections and which pins each section's wiper makes contact with. He would then have to match each terminal and wiper section with the VFO-820's schematic so he wires it correctly and the proper Functions works as the switch is rotated. If all this isnot done then it would be very easy wire the switch wrong even if the switch fits fine in the VFO. Another thing is the replacement switch appears to have "splines" and a "split" shaft for the knob. The split shaft allows the shaft to be spread apart to provide "friction" to hold the knob on the shaft without set screws. The VFO-820 shaft is solid and the VFO knob uses set screws. I've tried using set screw knobs with splines/split shaft switches before. Some work but then again some don't. Those that don't work tend to "appear to work" but sooner rather than later, the knob wobbles and comes lose since the set screw can't hold the knob firmly to the shaft due to the splines and split shaft.

Just my 2 cents.

44666. Need: main dial for 520 & battery cover for 930

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)

From: Walter Treftz
Topic: 44666 Message: 44666

OK, 2 problems here.
 One, I need to know a source for the tuning dial
(the 0-100 dial behind the main tuning knob (mine is bent)
and two, a source for the small top cover plate over the memory battery
compartment on the 930SAT.
Also, is the 520 tuning dial supposed to be loose (slip) on the shaft that
mounts on the main tuning shaft? Mine does (can always put a dab of
epoxy if its supposed to be rigid). Otherwise want to just replace the entire
tuning scale plate.
     Anyone got a junker that they're parting out would solve both my problems.

Wes,

He is saying "function switch" , not bandswitch. The bandswitch could be
a coupler off just a bit, but I'm not sure about the function switch. I
too am curious as to thoughts.

Yes - the Function switch on the external VFO is the culprit. It works when sitting on the edge as I mentioned, but it doesn't work when it seats completely where it's supposed to.

Any ideas from anyone?

Go to ebay and search on 3 pole 4 position (3P4T) rotory switches
(non-shorting).

Should find a lot of phenolic, ceramic and enclose styles at low
prices.

Remember depending on the radio that you have four 1/2 watt or
two 1 watt in parallel for 2 watts dissipation.

<ts-520_820_530_ 830@yahoogroups. com> wrote:

Terrry,
The cathode resistors are only 1/2 watt aren't they ?

On 9/16/2013 11:25 AM, wagstw46@... <mailto:wagstw46 @...>
wrote:

There is no way you can mis- tune the finals and blow a
cathode resistor.

I showed the math to you. If it was possible to see
350ma in a mis-tuning event then P = I squared R.

.350 x .350 x 5 = 0.61 watts.

A 2 watt resistor can run dissipating .61 watts
forever.

What plate current level do you think could be
attained in a mis-tuning event? What happens to the
HV power supply voltage at that current level? What
is the transformer Secondary power and what is the
Primary power at that current level? What happens
to the transformer primary fuse?

Even if it was possible to see a 700ma event then
.700 x .700 x 5 = 2.45 watts. A 2 watt resistor
will run a very very long time dissipating 2.45
watts.

Cathode resistors never blow due to mis-tuning of
any kind. They blow most certainly from tube arc
over.

Re: hand mic question
Tue Sep 17, 2013 5:07 am (PDT) . Posted by:
"Don Allen" w9cw

The best hand mic in my experience for the 530 and 820, as well as the
520 and 830, is the Shure 414. A bit hard to find these days, but it's
an excellent mic and its element is very similar to the Shure 444 desk mic.

New video
Tue Sep 17, 2013 7:01 am (PDT) . Posted by:
"Mike" w5rkl
Good morning,

I uploaded a new video to my folder on Gordon's webserver. The following
link will take you to the video:

http://www.n6wk. com/w5rkl/ Grid%20Voltage/ Grid%20voltage% 20changes% 20based%20on%
20sine%20wave% 20voltage% 20levels. wmv

This video briefly explains a sine wave, what a sine wave looks like,
the positive half and the negative half segment of the sine wave, and
the different degrees throughout the sine wave cycle.

The video also shows/discusses what the terms "Peak Voltage" AND "Peak
to Peak" voltages are when referenced to a sine wave cycle and what each
term means. These are terms that you need to know and what they mean so
you will understand what a discussion is about when the terms are used.

The remainder of the video discusses how the GRID voltage changes based
on the sine wave cycle voltages that occur throughout the sine wave
cycle.The video also explains that the GRID BIAS voltage applied to the
grid, -4 volts in the example shown in the video, DOES NOT CHANGE
throughout the entire applied signal's sine wave cycle!!! This is
important to fully understand!!

Walt,
I have a dial. It is metal with a brass insert in the center. Is this the dial that is loose? It should have 2 screws in it to tighten to the outer shaft. That shaft turns to adjust center of freq. Send me an Email off group with your mailing address and I will send the dial. dlbowders (at) nepower (dot) coop. I am not sure about this new format. I hope this posts.

Go to ebay and search on 3 pole 4 position (3P4T) rotory switches
(non-shorting).

Should find a lot of phenolic, ceramic and enclose styles at low
prices.

Topic: 44666 Message: 44668

Walt,

The 520(S) silver dial right behind the main VFO knob..should slip only when moved by hand...it is used along
with the "calibrator signal" to get correct frequency reading across the dials range...as it is not totally linear from
one end of its range to the other. The "other" one...white...with numbers from "0 to 600" should NOT slip. It is held to the
gear train by one screw.

Walt,
I have a dial. It is metal with a brass insert in the center. Is this the dial that is loose? It should have 2 screws in it to tighten to the outer shaft. That shaft turns to adjust center of freq. Send me an Email off group with your mailing address and I will send the dial. dlbowders (at) nepower (dot) coop. I am not sure about this new format. I hope this posts.

Remember depending on the radio that you have four 1/2 watt or
two 1 watt in parallel for 2 watts dissipation.

Terrry,
The cathode resistors are only 1/2 watt aren't they ?

On 9/16/2013 11:25 AM, wagstw46@... <mailto:wagstw46 @...>
wrote:

There is no way you can mis- tune the finals and blow a
cathode resistor.

I showed the math to you. If it was possible to see
350ma in a mis-tuning event then P = I squared R.

.350 x .350 x 5 = 0.61 watts.

A 2 watt resistor can run dissipating .61 watts
forever.

What plate current level do you think could be
attained in a mis-tuning event? What happens to the
HV power supply voltage at that current level? What
is the transformer Secondary power and what is the
Primary power at that current level? What happens
to the transformer primary fuse?

Even if it was possible to see a 700ma event then
.700 x .700 x 5 = 2.45 watts. A 2 watt resistor
will run a very very long time dissipating 2.45
watts.

Cathode resistors never blow due to mis-tuning of
any kind. They blow most certainly from tube arc
over.

The best hand mic in my experience for the 530 and 820, as well as the
520 and 830, is the Shure 414. A bit hard to find these days, but it's
an excellent mic and its element is very similar to the Shure 444 desk mic.

New video

Tue Sep 17, 2013 7:01 am (PDT) . Posted by:
"Mike" w5rkl
Good morning,

I uploaded a new video to my folder on Gordon's webserver. The following link will take you to the video:

http://www.n6wk. com/w5rkl/ Grid%20Voltage/ Grid%20voltage% 20changes% 20based%20on% 20sine%20wave% 20voltage% 20levels. wmv

This video briefly explains a sine wave, what a sine wave looks like, the positive half and the negative half segment of the sine wave, and the different degrees throughout the sine wave cycle.

The video also shows/discusses what the terms "Peak Voltage" AND "Peak to Peak" voltages are when referenced to a sine wave cycle and what each term means. These are terms that you need to know and what they mean so you will understand what a discussion is about when the terms are used.

The remainder of the video discusses how the GRID voltage changes based on the sine wave cycle voltages that occur throughout the sine wave cycle.The video also explains that the GRID BIAS voltage applied to the grid, -4 volts in the example shown in the video, DOES NOT CHANGE throughout the entire applied signal's sine wave cycle!!! This is important to fully understand!!

44669. Re: hand mic question

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-18 01:23:59 UTC
From: <km5wx@...>
Topic: 9016 Message: 44669

Thanks for the info guys. I guess I have to just keep trying to find one. How do I go about checking the mic impedance? I have several old 11 meter mics but no idea what the z is. They're not marked. I looked for a heil element to put in one but they're also hard to find. Thanks again Richard KM5WX

44670. Four 1N4004 diodes, five minutes soldering, and a little hope later...

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-18 03:03:03 UTC
From: Wes Will
Topic: 9016 Message: 44670

And once again the TS-520SE is back up and running just fine.

The DG-5 freq counter is still inoperative, when plugged in to the radio. I did a fast on-off and in the fraction of a second heard the 14V section of the power supply board start to sizzle. I cannot figure what could be wrong with that thing. YET.

The modification of the odd rectifier board, to add the side-tone bias connection via a 100K ohm resistor tacked to R9 worked a treat. (? Pretty sure it's R9, and the new resistor would be what should have been there as R10.)

The 300 PIV / 1 A 1N4004 diodes are a perfect replacement for the V06B diodes originally in there. Possibly better, since the same on/off of the rig with the DG-5 on it and V06B original diodes in there resulted in four bad diodes, and two burned traces on the rectifier board. The 1N4004 units held their own, and didn't blow or take anything out with themselves, unlike the OEM parts.

I'll be tuning up the transmitter into the dummy load tomorrow, when I'm less fatigued. Been a bit of a day for me, all around, and I didn't think I was even going to be able to snatch the five minutes for this repair. Tomorrow is smarter for working with an unfamiliar transmitter. I've got to try to remember how to load a tube rig, using the instructions from here. Don't want to blow a final now that I'm >this< close to having a working rig.

Yes Deoxit spray and canned air. I also like to use some Deoxit Fader Type F lube after cleaning. It is made for carbon trace pots and it helps maintain good smooth and quiet action for longer time after pot is cleaned. If you dont have any dont worry about it at this time. Just spray and exercise pot thru its full range multiple times and blow out with canned air. Do this with power off.

OK as I understand what you are saying you are speaking in the mic and getting some flicks of ALC and when you increase the mic gain more you reach a point where you lose the flicks of ALC and as you increase the mic gain past that spot you get flicks but much higher than you would like to see. Is this correct?

Try this to see if you are losing ALC indication or losing modulation.

Flip the meter to Ip or RF and watch the meter as you perform the same increase in mic gain. See if at the same place you were losing ALC you also lose Ip or RF indication. If you do then you know it is likely a bad spot on the mic gain pot. The peaks on IP and RF meter position will be different than what you observed on ALC but dont worry about that.

If so, you lose Ip and RF like you do ALC I would try cleaning the mic gain pot as a first step.

Also what kind of ALC indication are you trying to attain on voice peaks?

What position are you trying to run the Mic gain at (3, 4, 5, 6)?

Greg:

Are you talking about:

1. Setting the Car Level pot for a particular meter indication while adjusting the Drive control when loading the radio?

2. Speaking into the microphone in SSB mode and adjusting the mic gain pot as you speak for a particular amount of ALC indication on voice peaks?

When you adjust the mic gain there should be no ALC indication unless you are speaking into the microphone in LSB or USB mode.

Hi
My TS 520 has a dead spot when trying to adjust the ALC level. The dead spot is where I would like to set ALC. Probably in the mic adj . I turn the mic control clockwise and the meter needle moves to the right to a point where it drops back to zero. If I continue to turn clockwise the needle will bounce back up but then is out of range. Is there a fix for this.

Topic: 44672 Message: 44672

Has any kind ham got these errata notices which would be in 1983 and 1984 QST? The original article is available te OK.
I did this mod 3 years ago and there are one or two minor problems I would like to sort out.
Mainly with the poor Pi network on certain bands. It can be very tough on the 6146B's hat I use even with an upgraded fan and better air flow around the final.
I simply cannot be satisfied with a 50% final amp efficiency.
I am still looking for ideas to improve the front end S/N ratio. It is definitely noisier than my home brew RX on 14 MHz and I am a bit suspicious of the Rf stage source follower as a potential noise source and cross mod inducer.
Has anyone tried one of QST's hybrid cascodes as an RF stage upgrade?

Topic: 44675 Message: 44675

Good day! I have owned a TS-820 for over 10 years now and have given it many modifications in that time. These include the QST WARC bands, though the 18 Mhz mod is pretty poor as they final efficiency is low on that band.
Does anyone have a copy of the various errata published in QST during 1983 and 1984 to the original WARC conversion article in Feb 1983?
I still have the original article but not the corrections. It would be good to go through them in case I've missed something.

I have noticed that the TS-820 needs quite a high output microphone for SSB and a Hi Z model is the only way to go. However I use a modified Genius computer microphone with a small x10 built in amplifier. This works very well indeed. It needs a small internal battery, but since I use PTT this has a very long life.
It is noticeable just how many users have problems with the wafer switches over time, this is one of the worst features of the quality control of this radio and mine is no exception.
2 have been replaced entirely and I still need to fix the AGC switch properly as the rocker switches can be fragile too.
I have done the counter mods but the counter problems also seem to stem from band switch problems too. It is noticeable that if the counter pays up above 14 MHz cleaning the band switch can often get things going again.
My rig uses 6146B's in the final and has an upgraded fan and improved air circulation in the final area, but I am still considering making some new Pi network inductors for the output circuit. The original Kenwood design left quite a lot to be desired in that area.
If I get this done I'll post the details, after all an extra 20 or 30 watts output and less heat is not a bad idea.
My rig came with the CW and SSB filters and has had the RX front end mods done as well as
most other published changes. However as a lifelong home brewer, I am NOT entirely happy with the original RF stage. The extra source follower buffer bothers me a bit!
Has anyone tried a Norton of Hybrid cascode replacement for the original RF stage?

44677. DFC-230 for parts or possible repair

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-18 06:00:19 UTC
From: DBRogers
Topic: 44677 Message: 44677

A few years ago I bought a non-working DFC-230 as a parts unit to back up the two DFC-230 units that I use with my TS-130S and TS-130V. They are also used with the TS-830S, TS-530S and TS-120S. It has been about 5 years and the two good units are still working just fine, so I would like to sell the parts unit.

It seems to be complete except for the 4 screws that hold the circuit board to which the mic cord is attached (which also seems to be the problem area), and one foot is missing. It does not work.

If you need this, you know what it is. If you don’t know what it is, you probably don’t need it.

I would like $30.00 for it shipped within the USofA. Payment would have to be by USPS postal money order.

DId I mention that it does not work?

Thanks,

David, WA7ZYQ

It sounds like your efficiency issues are primarily due to less than optimum Q due to compromise tank L/C ratios on the Warc bands.

Instead of using relays and tapping on the existing tank coil today it would be pretty easy to buy an entire TS530 or TS830 PA cage with all the components designed for WARC operation. Might be fun project to swap out existing unit. This way have correct tank coil, tank caps, fixed padders etc for all the bands.

Might give Bob Mansker a try to see what he gets for a PA unit. Also show up on Ebay on regular basis.

Have you ever measured the RF drive levels at the control grids of the 6146 finals since you had to home brew Driver stage tank circuits for the Warc band. Are you able to easily get full scale ALC indication on the WARC bands without having to run Car Level pot full open? Easy to measure the RF drive. Should see something like 45 to 47rms rf volts.

Lastly I wonder if you would be better off using the Plate Choke from the TS530 or TS830? I have never looked at the original 820 choke to see if any series resonant holes near the WARC bands? Easy to do with GDO with choke shorted to simulate the shunt capacitance it sees in circuit. The TS830 solenoid wound choke has a hole close to 25mhz that makes me a little nervous.

I forgot to comment.

Are you talking about the TS820 having two much gain ahead of the 1st Mixer? If so, sounds like something that Bob Sherwood has discussed often. Perhaps you have read his published articles on using a cascode amp for gain redistribution?

Kenwood after the TS520 attempted to addressed this problem by adding a diode switched capacitive voltage divider rf attenuator between the RF amp and buffer before the 1st mixer. It is controlled by the bandswitch and shunts some of the RF signal from Drain of Q2 RF amp to ground on the low bands and allows full gain on 10 meters.

In the TS820 it is diodes D4/D5 and capacitors C24/C25. If you are experiencing problems on 160 or 80 meters might want to make sure this circuit is working. Also make sure have good molex pin conneciton at RF-1 Pin 6 B4. I have never found it non functioning in a TS820, but I have in a TS520S.

I dont live in an area where I have to worry about front end being grossly overloaded by broadcast transmitters. Very seldom have to use the front panel switched 20db attenuator.

Also, maybe my ear is just less discriminating?

I have noticed that the TS-820 needs quite a high output microphone for SSB and a Hi Z model is the only way to go. However I use a modified Genius computer microphone with a small x10 built in amplifier. This works very well indeed. It needs a small internal battery, but since I use PTT this has a very long life.
It is noticeable just how many users have problems with the wafer switches over time, this is one of the worst features of the quality control of this radio and mine is no exception.
2 have been replaced entirely and I still need to fix the AGC switch properly as the rocker switches can be fragile too.
I have done the counter mods but the counter problems also seem to stem from band switch problems too. It is noticeable that if the counter pays up above 14 MHz cleaning the band switch can often get things going again.
My rig uses 6146B's in the final and has an upgraded fan and improved air circulation in the final area, but I am still considering making some new Pi network inductors for the output circuit. The original Kenwood design left quite a lot to be desired in that area.
If I get this done I'll post the details, after all an extra 20 or 30 watts output and less heat is not a bad idea.
My rig came with the CW and SSB filters and has had the RX front end mods done as well as
most other published changes. However as a lifelong home brewer, I am NOT entirely happy with the original RF stage. The extra source follower buffer bothers me a bit!
Has anyone tried a Norton of Hybrid cascode replacement for the original RF stage?

Lars:

The compressor is one of the better ones if aligned properly. It is kind of unusual circuit. It is not a clipper in the IF chain like the TS830. It uses a Balanced Mod to to convert your mic audio into a 455khz DSBSC signal and processes it and then a Product Detector to convert it back to audio for input to your SSB Balanced Modulator.

One of the biggest problems is people tweak on it without test gear and number one thing I find is they have tried to follow the procedure in the Service Manual and it is flawed. As I said this thing works by taking audio and applying it to its own Balanced Modulator that uses 455 khz as the LO. The manual has you set the LO for 451khz. This is outside the 455khz ceramic IF filters frequency response curve. Have to get the signal into the pass band of the ceramic filter chain that follows. It is possible to have a bad filter, but I have never seen one.

If you have a Frequency Counter you could just try setting TC-4 on IF board for 455kz at TP-3 and see what effect that has. You really cant hurt anything by making this simple adjustment. I suppose with no counter you could listen to yourself on the Moni with headphones and make small step changes on TC-4 to see if any improvement.

To really align it you need in addition to a freq counter a good stable AF generator and a means of accurately measuring low level AF signals. AC millivolt meter is easiest, but O-scope also will work.

44685. CARRIER instability on the TS-520S

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-18 14:58:47 UTC
From: Chris Maness
Topic: 44685 Message: 44685

I purchased it from the Salvation Army back in 2009, and the previous owner went SK in 1995 (from the S.S. number on the rig). So I think it is safe to assume my TS-520S has not been on very much in the past twenty years at least. My experience has taught me that it is not good for a rig to sit idle for years on end. Monday I was finally able to get this radio going 100% with a bad diode on the balanced mixer. Since fixing it, I have been using it a lot, and it seems that the CARRIER has shifted frequencies again. I had adjusted this back in 2009, but last night I was hearing CW notes on both sides of the carrier AGAIN. I guess carrier oscillator has gone squirrely due to running it so much the last few days. However, there are only two parts that control the frequency. The crystal or the trimmer cap. Is it possible that one of these parts have not aged well. I am hopping it will settle down. Yesterday I ordered a CW filter for the radio, should I wait tell this comes before I adjust the CW carrier against the xtal filter skirt or adjust it now and expect that it will fall in line with the new CW filter. The USB/LSB is fine, so I know those two rocks are ok. I only hear a beat note on one side of the carrier in the SSB modes. Should I replace either the trimmer or the Xtal if it keeps drifting around?

Watcha think?

Thanks,
Chris Maness

Terry thank you so very much!
I tuned my FT-847 to same freq as the 820 (10m) put on headphones, and without turning heater on, I got a nice ssb signal, then after following your instruction, I turned the TC4 abt 20-25 degrees, and the sound got better and better, so now, with compressor at 12 a'clock, its brilliant!!
I even tried to turn it up to full, and also the mike gain, and it still sounds great, but strong!!
No distortion at all!!
Though, I would say that 12 a'clock on compressor, and about 2-3 a'clock on mike gain, sounds just perfect!
I hope to be able to check in on net Saturday, and hear what all you guys think.
My friend Dave, who owns this radio is a lucky s.o.b, the radio is in near mint condition, both inside and out!
Terry thanks again!!

OK Lars a cheap and dirty fix. I have also done this quick adjustment a time of two just to be able to see if the processor was capable of working until I could take the time to do a full alignment. The real test will come with chasing DX barefoot. I generally dont like to run a lot of compression and almost never do so state side. The 820 manual advises that only use for DX work. I must admit that the 820 processor generally sounds better than the 830.

Maybe some day we can get this TS820 sevice manual revised. Perhaps could add a chapter on alternate ways to perform certain steps absent the KW recommended test gear.

For about 90% of the steps there are good ways to perform them and several alternate ways to perform them. Very few "Only" ways to perform most of these alignment steps. I have been in argument or two about that on other forums. Kenwood doesnt tell you the alternate ways. They just list the test gear they used. That is understandable.

Hopefully not too many more golden screw drivers have been in what sounds like a real beauty.

Have fun

How do you know the Carrier Osc frequency is drifting? Are you watching the Carrier Osc frequency at the CAR term post at the Gen Board with a stable Freq Counter?

Could it be the bal trim pot VR-1 and bal trim cap TC-1 on the Balanced Mod are dirty? Ceramic trim caps are very touchy even from moving the rig around on the bench.

No my assertation* *was not that scientific. Before I made my fix it was working fine. However, now I am hearing CW on both sides of the carrier. However, as I am composing this I am realizing that changing the capacitor on the balanced modulator might have slightly effected (or pulled) the frequency of the carrier crystal. In that case I just need to readjust and be done with it.

To: TS-520_820_530_830@yahoogroups.com
Subject: DFC-230 for parts or possible repair

A few years ago I bought a non-working DFC-230 as a parts unit to back up the two DFC-230 units that I use with my TS-130S and TS-130V. They are also used with the TS-830S, TS-530S and TS-120S. It has been about 5 years and the two good units are still working just fine, so I would like to sell the parts unit.

It seems to be complete except for the 4 screws that hold the circuit board to which the mic cord is attached (which also seems to be the problem area), and one foot is missing. It does not work.

If you need this, you know what it is. If you don’t know what it is, you probably don’t need it.

I would like $30.00 for it shipped within the USofA. Payment would have to be by USPS postal money order.

DId I mention that it does not work?

Thanks,

David, WA7ZYQ

You can adjust the BM trimmer pot and trimmer cap all day long and the Carrier Osc will never see it. There is a nice buffer stage in the way of that.

You cannot just adjust the trimmer pot and trimmer cap on one side band. Has to be done on both and it will be a compromise. Some call this adjusting the Carrier Suppression and others call it Carrier Balance. It is a back and forth iteration that takes multiple passes to get the carrier nulled equally low on each side band.

I usually do it in SSB mode with Mic gain turned down full CCW. Can load to full output power in CW and then switch to SSB and adjust.

Need to connect RF probe/VTVM at SO-239 and key mic or flip to send and adjust for a null in rf voltage on one side band and then flip to other and null again. Will find the trimmers interact and you have to off set and compromise for the best low rf voltage level flipping back and forth between LSB and USB. Will never get it to be zero on both side bands.

Hi Richard!
If it is a dynamic mic all you need is an Ohmmeter. Lo Z mics are in the range100 to 300 Ohms and Hi Z in the range 800 Ohms and up. Be sure that you have the right connections to the mic plug however as the TS-820 is not compatible with some Microphones.
Also the diagram of the connections in the manual is rather confusing.

I'm a Yaesu freak. That said, the Kenwood TS-520 I just bought (off eBay) has a problem. RX is indescribably delicious. There's no TX. Can only manage about 20ma idle and the plate doesn't really dip. (It sort of curtsies.) Nothing into the watt meter. Replacing the driver tube made no difference.

Can anyone offer a clue as to where I might start. Thanks.

-O'B.

I forgot to comment on your "assertation". Working on a Kenwood hybrid or any vintage radio isnt about scientific assertations. It is about testing and measuring.

When someone asks you how you know your Carrier Oscillator is drifting it isnt challenging your assertation. It is asking are you guessing, easter egging, using a flashlite or sniffing or....???

Lack of measuring and testing is how lots of crystals and ceramic trimmer caps and other good parts get needlessly replaced on forums like this one.

Also you cannot expect to make any adjustment in 2009 and expect it to be dead on today.This is especially true if the radio has been stored and or moved about. Even more so when that adjustment is done with a ceramic trimmer capacitor.

Try adjusting your LSB and USB carrier oscillator trimmer caps for the receive audio response you like. Check this by looking at your S-meter zero beat indication on LSB and USB. If you have your slow rythmic quiver at say S3 remember that. Now re-install the covers and place rig back in operating position. Check the zero beat again and not unusual to find it is now at S2 or S4 on LSB or USB or both. Very sensitive and touchy adjustments.
.

How do you know the Carrier Osc frequency is drifting? Are you watching the Carrier Osc frequency at the CAR term post at the Gen Board with a stable Freq Counter?

Could it be the bal trim pot VR-1 and bal trim cap TC-1 on the Balanced Mod are dirty? Ceramic trim caps are very touchy even from moving the rig around on the bench.

I purchased it from the Salvation Army back in 2009, and the previous owner went SK in 1995 (from the S.S. number on the rig). So I think it is safe to assume my TS-520S has not been on very much in the past twenty years at least. My experience has taught me that it is not good for a rig to sit idle for years on end. Monday I was finally able to get this radio going 100% with a bad diode on the balanced mixer. Since fixing it, I have been using it a lot, and it seems that the CARRIER has shifted frequencies again. I had adjusted this back in 2009, but last night I was hearing CW notes on both sides of the carrier AGAIN. I guess carrier oscillator has gone squirrely due to running it so much the last few days. However, there are only two parts that control the frequency. The crystal or the trimmer cap. Is it possible that one of these parts have not aged well. I am hopping it will settle down. Yesterday I ordered a! CW filter for the radio, should I wait tell this comes before I adjust the CW carrier against the xtal filter skirt or adjust it now and expect that it will fall in line with the new CW filter. The USB/LSB is fine, so I know those two rocks are ok. I only hear a beat note on one side of the carrier in the SSB modes. Should I replace either the trimmer or the Xtal if it keeps drifting around?

Watcha think?

Thanks,
Chris Maness

Chris:

OK using the receiver is an acceptable alternative method to adjust carrier suppression. Done it myself lots of times. If you cannot hear carrier on your bench with test receiver then not very likely a fellow hundreds of miles away will.

OK for starters you might want to make sure you have Zero dc volts at the BM terminal on Gen Board in CW mode with Car Pot turned full CCW.

Even though a germanium diode has theoretical barrier potential of approx 0.25vdc (where you will see milliamperes of forward current), below that level you can see ua leakage current down in the .10 to .20 vdc range. Not unusual to see couple hundred ua at that voltage level.

So I think first place to look is at BM to make sure you have Zero vdc with Car at full CCW position.

Thanks, that rules that cause out.

You cannot just adjust the trimmer pot and trimmer cap on one side band. Has to be done on both and it will be a compromise. Some call this adjusting the Carrier Suppression and others call it Carrier Balance. It is a back and forth iteration that takes multiple passes to get the carrier nulled equally low on each side band.

SSB is perfect. Problem is just in CW receive.

I usually do it in SSB mode with Mic gain turned down full CCW. Can load to full output power in CW and then switch to SSB and adjust.

Need to connect RF probe/VTVM at SO-239 and key mic or flip to send and adjust for a null in rf voltage on one side band and then flip to other and null again. Will find the trimmers interact and you have to off set and compromise for the best low rf voltage level flipping back and forth between LSB and USB. Will never get it to be zero on both side bands.

I use my FT-817 with no antenna for this. However, per my statement above. I balanced the carrier on Monday the day I replaced the diodes. I am getting a beat note on both sides of the carrier on CW receive only. I remember the cure for this one is to adjust TC1 on the

what's your HV reading on transmit? If it's normal 800v or more, then you have to check final and driver tube screen voltages at the tube sockets and those cathode resistors.

Subject: [TS-520_820_530_830] Need a clue...

I'm a Yaesu freak. That said, the Kenwood TS-520 I just bought (off eBay) has a problem. RX is indescribably delicious. There's no TX. Can only manage about 20ma idle and the plate doesn't really dip. (It sort of curtsies.) Nothing into the watt meter. Replacing the driver tube made no difference.

Can anyone offer a clue as to where I might start. Thanks.

I acquired a TS 530SP with an on/off switch wired into the counter board on connector #2 pin #9. Rather hacked at that. I removed it and reconnected wire to the connector and receive works fine on the affected bands. The owner had stated that it would not receive and readout was blank so he evidently did not do the mod. He is a Ham up north and was only interested in getting rid of it. It is in relatively good shape and has a 6 million serial no.and still has the KW inspection stickers inside dated 1989, so I think I may hold on to this rig but this is the second time I have run into this mod and do not know what benefit it could be. The other time was in a TS 830 several years ago. Same scenario. I know I do not get out much but I can not figure out what this would do other than shut down several bands. Why would you do that? I am getting to the point of not being surprised by any of the hack jobs but if someone has an opinion about this let me know. Wouldn't you just like to smack someone if you caught them?

Topic: 44701 Message: 44701

Group,

I need help aligning three components on my TS 820S. The plastic bandswitch coupler was broken, so I purchase a metal one from K4EAA. After breaking I think the coil pack board section of the bandswitch shaft and the final unit shaft became misalligned. Also, during disassembly I think the front panel bandswitch knob became misaligned.

As many in this group know on the 820S the front panel bandswitch knob is connected to the coil pack shaft via a 'chain' type linkage.

So, I am seeking guidance in how to align those three components: 1) front panel bandswitch knob, 2) coil pack section of the bandswitch shaft, and 3) the final section of the bandswich shaft.

I have, without success so far, tried to navigate through the Kenwood schematics. The schematic does show 4 wafer swiches in the final unit - SW1-SW4 - but does not indicate how they align with 6 wafer switches on the coil pack board (the switches have no reference designators), nor how they are mechanically aligned with the front panel linkage.

Yes, at least it seems that way. It is a bit hard to be sure since the "rf" gain control appears to actually be an IF gain control. Possibly that is why they put the front panel attenuator button in?
As a long time home brewer (my Ts-820 and an upgrade FRG-7 are the only commercial gear I have) I was a bit dubious about the whole design of the RF stage the use of a source follower to drive the mixer at Lo Z seems to me to be an invitation to increase front end noise.
That's why I asked about anyone using a Norton circuit or a Hybrid cascode as a replacement. The Hybrid would be much easier of course as it has a moderately high input impedance and is designed to use a transformer coupled output to the mixer.
I use the QST version as the 2nd IF in my latest receiver.

BTW I have upgrade all the FET's in the front end and done the suggested mixer mods as well. It improved things slightly but I guess I am a stickler for quiet receivers.
My favourite mode is "Antipodal Hop" skating low angle signals off the ionosphere to NZ's antipodes in the Western Mediterranean. This sometimes works when 20 for example sounds quite dead.
Do you have reference to Bob Sherwood's article? It would be very interesting to read.

Don:

That sounds like 11 meter mod. Anytime you are messing with B and C you are messing with the PLL divider logic. They usually reverse B and C.

Suggest you look at the PLL board Connector 2 Pin 2 "C" and make sure they have not cut the wire (white/purple) to it and placed switch in series with it. If you find wire has been cut and spliced and taped back who ever undid the mod probably just didnt discover all of it?

Could be wrong but sure sounds like it. What makes me mad is these guys are smart or clever enough to do this but do not use that knowledge in constructive manner. Sadly often these things are figured out and published by licensed ham operators. Same ones who would run 10KW amps.

I now own a nice TS820 with the digital display (the replacement green one). Really nice radio.Got it a few weeks ago and did the capacitor replacement plus clean up and added new final tubes and also a new 12BY7A. VFO drift is now under control and it really is one awesome radio. I have a chance to get a never used Remote VFO for it with the cable fairly cheap ($50).

Is there a reason why I need a remote VFO? What are the advantages of having one? It does not have a digital read out and is it possible to add one to it?

Here is the Sherwood article;

http://www.sherweng.com/documents/Present-dayReceivers-sm.pdf

The RF gain control is used to adjust the dc voltage to the AGC bus rail. RF-1 typically is set for 3.2 to 3.6vdc depending on the KW hybrid model. It is derived from the regulated 9vdc AVR board.

The AGC voltage is a dc control voltage that is fed to Gate 2 of the RF amp and IF amps dual gate mosfets. Dc bias is also applied to Gate 1 to set the quiescent operating point of these amps. A variable Dc control voltage is applied to Gate 2 of all the gain controlled devices.

At nominal 3.6vdc on Gate 2 these mosfets are turned on for best signal to noise ratio. Can get a little more gain out of them if you increase this voltage, but around 4 volts or so you are at the knee of the curve. The S-meter is a FET based voltmeter with the gate hanging on the AGC rail. With 3.6vdc on the rail the S-meter is adjusted to read Zero. Anytime the AGC rail voltage goes down the FET sees this and drives the S-meter up scale. This is why when you lower the RF gain setting the meter reads up scale. You have just lowered the AGC rail voltage and the gain of the RF and IF amp mosfet amps. So if you set the RF gain for an S9 indication it is going to take a signal stronger than S9 to move the meter up scale. At S9 you have lowered the AGC rail voltage to approx 2.0vdc. It would normally take a -73dBM or 50uv signal to produce a S-9 indication.

At nominal 3.6vdc on Gate 2 the AGC threshold is approx -115dBm or 0.40uv. The AGC detector diodes are back biased by -6vdc to set the threshold level. I use a very high impedance HP-410C VTVM to measure this.

There are two ways to vary the gain of the RF amp and IF amps. One is to lower the RF gain pot as I have mentioned and the other it to allow the AGC detector diodes to do it. With the AGC turned to Fast or Slow an off air signal is amplified by RF amp and IF amps. A sample of the RIF signal at last IF amp is fed to AGC detector diodes. They are in the base bias network of the AGC amp transistor. The collector of this transistor is hanging on the AGC bus rail that is fed thru a 2 meg resistor making it a high Z power supply. It cannot support any load. It normally only sees the Gate 2 high Z and the AGC time constant capacitors. So when the AGC detector diodes turn on the AGC amp transistor (acts like a variable load) it pulls the AGC rail down and the gain of the RF amp and IF amps is reduced and the S-meter drives up scale showing the relative strength of the received signal.

The RF attenuator is ahead of the RF amp and I think primarily there to address those high voltage signals at the SO-239 particularly on 160 and 80 meters.

Steve,

Make sure that you have or, can get the interconnecting cable. Hard to find the originals, but there are several sellers that make
a "modern" one using a 9 pin "socket saver."

  Having or wanting....hummmm. Most reasons for remote VFO is to work "split." Transmit on one freq...receive on another...or use the remote
VFO to substitute for the main VFO. to split the wear or...if it breaks..or just 'cause you want to. Read the manual...there are several combinations
available to you. When using the remote VFO and you have the proper selection made on the "function" switch...say for example...you are
using the remote VFO to control "transmit" frequency...when you transmit...the frequency the remote VFO is on will be displayed on your
820 digital readout. I find that the 820 remote VFO to be just fine...and accurate when calibrated according to directions in the manual.
The other Kenwood remote VFO...the VFO 230 is digital...commands a premium price...will work fine with the 820...but LORD help
you if it breaks (just my observation & opinion) I had one...not again

Subject: [TS-520_820_530_830] Why do I need a remote VFO for the Kenwood TS820?

I now own a nice TS820 with the digital display (the replacement green one). Really nice radio.Got it a few weeks ago and did the capacitor replacement plus clean up and added new final tubes and also a new 12BY7A. VFO drift is now under control and it really is one awesome radio. I have a chance to get a never used Remote VFO for it with the cable fairly cheap ($50).

Is there a reason why I need a remote VFO? What are the advantages of having one? It does not have a digital read out and is it possible to add one to it?

Don,

  This is a common "mod"....it's called "CB HACK," or "FREE BANDING." Off the top of my head, if the switch was say in
the "on" position and the bandswitch was say in the 28 to 29Mhz range...and the +0.5 switch was pushed...you could receive and
transmit from about the low 26Mhz to ????which covers the CB frequencies. I have seen a few that looked "factory" but then,
a few that looked put together by blind, drunk monkies. Also, you never know what else may be wrong...by adjustment
by the "golden screwdriver."

Subject: [TS-520_820_530_830] What would this mod accomplish ?

I acquired a TS 530SP with an on/off switch wired into the counter board on connector #2 pin #9. Rather hacked at that. I removed it and reconnected wire to the connector and receive works fine on the affected bands. The owner had stated that it would not receive and readout was blank so he evidently did not do the mod. He is a Ham up north and was only interested in getting rid of it. It is in relatively good shape and has a 6 million serial no.and still has the KW inspection stickers inside dated 1989, so I think I may hold on to this rig but this is the second time I have run into this mod and do not know what benefit it could be. The other time was in a TS 830 several years ago. Same scenario. I know I do not get out much but I can not figure out what this would do other than shut down several bands. Why would you do that? I am getting to the point of not being surprised by any of the hack jobs but if someone has an opinion about this let me know.
Wouldn't you just like to smack someone if you caught them?

The VFO-230 is not compatible nor will it work with the TS-820 series transceivers.

The VFO-230 operates over a frequency range between 5.400Mhz and 6.100Mhz. The internal VFO in the TS-820 series and the external VFO-820 operate over a frequency range between 4.900Mhz and 5.500Mhz.

The VFO-240 also is not compatible with the TS-820 series transceivers for the same reason, the VFO frequency range is wrong.

Terry
Please let me start at the beginning. My TS 520 has worked very well on 10 meters this summer. I have contacts from New York to California and down into S. America using a dipole at 30'. I just received my General license a week ago . I have a OCF antenna and tuner but the antenna is still on my work bench.
The problem started a few days ago with a dead spot on ALC adjusting Mic gain. It progressed over a couple days to no ALC indication at all adjusting mic. I tried what you told me to do and checked RF and IP. No movement there either.
The receiver is not working correctly either. I can receive JJY/WWV at 28.00. At 28.150 I hear what sounds like a digital signal. If I flip thru all the bands I can hear the same signal without changing frequencies. I can also hear what sounds like a aircraft weather report. I hear some digital signals on some frequencies but no SSB or LSB.
Ya gotta tell me doc, how bad is it?

Yes Deoxit spray and canned air. I also like to use some Deoxit Fader Type F lube after cleaning. It is made for carbon trace pots and it helps maintain good smooth and quiet action for longer time after pot is cleaned. If you dont have any dont worry about it at this time. Just spray and exercise pot thru its full range multiple times and blow out with canned air. Do this with power off.

wagstw46@... writes:

OK as I understand what you are saying you are speaking in the mic and
getting some flicks of ALC and when you increase the mic gain more you reach a
point where you lose the flicks of ALC and as you increase the mic gain
past that spot you get flicks but much higher than you would like to see. Is
this correct?

Try this to see if you are losing ALC indication or losing modulation.

Flip the meter to Ip or RF and watch the meter as you perform the same
increase in mic gain. See if at the same place you were losing ALC you also
lose Ip or RF indication. If you do then you know it is likely a bad spot on
the mic gain pot. The peaks on IP and RF meter position will be different
than what you observed on ALC but dont worry about that.

If so, you lose Ip and RF like you do ALC I would try cleaning the mic
gain pot as a first step.

Also what kind of ALC indication are you trying to attain on voice peaks?

What position are you trying to run the Mic gain at (3, 4, 5, 6)?

Greg:

Are you talking about:

1. Setting the Car Level pot for a particular meter indication while
adjusting the Drive control when loading the radio?

2. Speaking into the microphone in SSB mode and adjusting the mic gain pot as you speak for a particular amount of ALC indication on voice peaks?

When you adjust the mic gain there should be no ALC indication unless you are speaking into the microphone in LSB or USB mode.

Hi
My TS 520 has a dead spot when trying to adjust the ALC level. The dead spot is where I would like to set ALC. Probably in the mic adj . I turn the mic control clockwise and the meter needle moves to the right to a point where it drops back to zero. If I continue to turn clockwise the needle will bounce back up but then is out of range. Is there a fix for this.

From: Chris Maness
Topic: 44713 Message: 44713

Ok, I am now thinking that issue was never resolved the first time I was messing with this radio in 2009. I have made some measurements. I don't have the 500Hz CW filter installed, so this all may be moot when it is.

1. Listening to the 25kHz calibration carrier in SSB gives me some unexpected results. The passband of this radio is VERY wide. It sounds beautiful with the local rag chew groups that are running hi-fi sound. The passband is almost 4kHz wide.

2. Since I don't have the CW filter, my bandwidth is so wide the beat note on the other side of the carrier shows up as I tune through the 25kHz calibration carrier. I have uploaded a you tube video since some folks might not understand what I mean by this, and I want to make sure I am very clear about what is going on here. Here is the video:

http://youtu.be/Ate02ICbLmw

3. I am thinking that this might be a defective multipole crystal passband filter. It sounds beautiful on SSB, but so wide I am hearing a note on both sides of the carrier. This problem will probably be moot when I install the CW filter, but I am thinking I still might not want to be running so wide on SSB.

4. Now I fully remember all the problems I was having with this radio back in 2009, and I still want to keep her and fix her. I now have the biggest problem with the radio behind me, so moving on to this conundrum.

Steve,

Make sure that you have or, can get the interconnecting cable. Hard to find the originals, but there are several sellers that make a "modern" one using a 9 pin "socket saver."

  Having or wanting....hummmm. Most reasons for remote VFO is to work "split." Transmit on one freq...receive on another...or use the remote VFO to substitute for the main VFO. to split the wear or...if it breaks..or just 'cause you want to. Read the manual...there are several combinations available to you. When using the remote VFO and you have the proper selection made on the "function" switch...say for example...you are using the remote VFO to control "transmit" frequency...when you transmit...the frequency

the remote VFO is on will be displayed on your
820 digital readout. I find that the 820 remote VFO to be
just fine...and accurate when calibrated according to directions in the manual.
The other Kenwood remote VFO...the VFO 230 is digital...commands a premium price...will
work fine with the 820...but LORD help
you if it breaks (just my observation & opinion) I had one...not again

Subject: [TS-520_820_530_830] Why do I need a remote VFO for the Kenwood TS820?

I now own a nice TS820 with the digital display (the replacement green one). Really nice radio.Got it a few weeks ago and did the capacitor replacement plus clean up and added new final tubes and also a new 12BY7A. VFO drift is now under control and it really is one awesome radio. I have a chance to get a never used Remote VFO for it with the cable fairly cheap ($50).

Is there a reason why I need a remote VFO? What are the advantages of having one? It does not have a digital read out and is it possible to add one to it?

For instance, Lars' message around 0730-ish this morning just arrived, which made the reply I received in near-real-time from Terry (some time after 0800) make a lot more sense.

Those two aren't the only messages which have come in to my in-box today in reverse or otherwise scrambled order. Several threads are pied like that so far.

Is there some blockage in the system? Does Yahoo hate me for denying them the opportunities for more Spam in my in-box, or is it simply that I'm a Luddite when it comes to this stuff, preferring that text messages be TEXT messages without a lot of fluff on top?

I do not ever use the web page interface, I find such things to be excessively loaded with "features" which I never need, want, nor use.

I just read email. Words in a row. I like it that way.

I have seen references to "the changes" to "the system," which I am assuming mean something to do with the way the Yahoo web site for forae like this one is set up. Is this related? Just started in the last day or so,

My own MailMan mailing list server (sits in the rack in the basement, just runs, has done so for years) and Postfix SMTP and Dovecot IMAP set-up doesn't deliver mail backwards through time; or if it does none of the folks using it have ever mentioned it to me. Since none of my systems have been down at all, I am at a loss to understand how this recent phenomenon could occur without positing some sort of error at Yahoo.

Any Clues? Or is it just me?

Wes,

This sort of thing has been happening for ages, your system has just been adopted into the "whenever yahoo decides box" LOL. I may not get any messages for days and then a huge backlog of messages arrive all jumbled up. Don't take it personally LOL. I'm pretty sure Terry, is referring to the Outlook change, it took me a while to get my system sorted again.

Please let me start at the beginning. My TS 520 has worked very well on 10 meters this summer. I have contacts from New York to California and down into S. America using a dipole at 30'. I just received my General license a week ago . I have a OCF antenna and tuner but the antenna is still on my work bench.

The problem started a few days ago with a dead spot on ALC adjusting Mic gain. It progressed over a couple days to no ALC indication at all adjusting mic. I tried what you told me to do and checked RF and IP. No movement there either.

The receiver is not working correctly either. I can receive JJY/WWV at 28.00. At 28.150 I hear what sounds like a digital signal. If I flip thru all the bands I can hear the same signal without changing frequencies. I can also hear what sounds like a aircraft weather report. I hear some digital signals on some frequencies but no SSB or LSB.

Ya gotta tell me doc, how bad is it?

Yes Deoxit spray and canned air. I also like to use some Deoxit Fader Type F lube after cleaning. It is made for carbon trace pots and it helps maintain good smooth and quiet action for longer time after pot is cleaned. If you dont have any dont worry about it at this time. Just spray and exercise pot thru its full range multiple times and blow out with canned air. Do this with power off.

OK as I understand what you are saying you are speaking in the mic and getting some flicks of ALC and when you increase the mic gain more you reach a point where you lose the flicks of ALC and as you increase the mic gain past that spot you get flicks but much higher than you would like to see. Is this correct?

Try this to see if you are losing ALC indication or losing modulation.

Flip the meter to Ip or RF and watch the meter as you perform the same increase in mic gain. See if at the same place you were losing ALC you also lose Ip or RF indication. If you do then you know it is likely a bad spot on the mic gain pot. The peaks on IP and RF meter position will be different than what you observed on ALC but dont worry about that.

If so, you lose Ip and RF like you do ALC I would try cleaning the mic gain pot as a first step.

Also what kind of ALC indication are you trying to attain on voice peaks?

What position are you trying to run the Mic gain at (3, 4, 5, 6)?

Greg:

Are you talking about:

1. Setting the Car Level pot for a particular meter indication while adjusting the Drive control when loading the radio?

2. Speaking into the microphone in SSB mode and adjusting the mic gain pot as you speak for a particular amount of ALC indication on voice peaks?

When you adjust the mic gain there should be no ALC indication unless you are speaking into the microphone in LSB or USB mode.

I forgot to ask.

What Mosfets did you use in the front end?

We are limited state side to NTE222 and NTE454. I have a small supply of NOS 3N211 and 40673. A 3SK48 was used by some folks and it was also used in VHF pre-amps with approx 2.0 NF, but no longer available. I have two supposed NOS 3SK48 and plan to use in one of my own rigs to see if any measurable difference.

VHF clubs use to have NF testing day where fellows would bring their homebrew VHF pre-amps and gain and NF would be measured with correct procedure and calibrated test gear. None of this " it is much quieter" subjective reporting stuff. A 3SK48 was popular device for these club pre-amps.

I once had a 820 on the bench where someone had tack soldered X-package BF981 devices on the foil side of the board. These report typical NF of 0.7 at low current?

Also, I am not familiar with the Mixer Mods you mention? Would be interested if could point me to info on this.

Lastly have you looked at the RX Level Diagram in the Service Manual? It shows you were the gain is at for the RF and IF amps. The dB levels are not what you would measure but what you would inject at the given test point to obtain 50mw output across 8 ohm dummy load at audio output. For example on 20 meters you would inject 1.58uv at gate of 3SK35 RF amp and inject 50uv at drain of the Rf amp. So should have approx 30dB gain across the RF amp.

I think sometimes folks dont understand difference between maximum gain and maximum signal to noise ratio when making these mods and device substitutions and really have no way to do any before and after measuring. Ends up being "feel good" engineering. I have had TS-520 rigs here that were nice and quiet on 40 meters and nice to listen to the audio only to find that they had set the RF-1 down around 2.75vdc or so.

Yes, at least it seems that way. It is a bit hard to be sure since the
"rf" gain control appears to actually be an IF gain control. Possibly
that is why they put the front panel attenuator
button in?
As a long time home brewer (my Ts-820 and an upgrade FRG-7 are the only
commercial gear I have) I was a bit dubious about the whole design of
the RF stage the use of a source follower to drive the mixer at Lo Z
seems to me to be an invitation to increase front end noise.
That's why I asked about anyone using a Norton circuit or a Hybrid
cascode as a replacement. The Hybrid would be much easier of course as

it has a moderately high input impedance and is designed to use a transformer coupled output to the mixer.
I use the QST version as the 2nd IF in my latest receiver.

BTW I have upgrade all the FET's in the front end and done the suggested mixer mods as well. It improved things slightly but I guess I am a stickler for quiet receivers.
My favourite mode is "Antipodal Hop" skating low angle signals off the ionosphere to NZ's
antipodes in the Western Mediterranean. This sometimes works when 20 for example sounds quite dead.
Do you have reference to Bob Sherwood's article? It would be very interesting to read.
Thanks for your help.

If you want to very easily see and measure and adjust your passband response:

Go here and download Spectrogram Version 5.17 Audio Spectrum Analyzer Software to your laptop.

http://w5big.com/spectrogram.htm.

1. Make a patch cord for your headphone jack to the mic/line input to your sound card. I bought a Radio Shack cord with 1/4 inch phone plug on one end and mini-plug on the other end. I cut it in half and installed a log taper audio pot in series to use as a padder. Allows me to set the input level to my sound card to give approx 35 db peak so I dont overload the sound card. You will see dB displayed on the X-axis and frequency on the Y-axis. If you set the gain to your sound card too high the display will start to lift off the Y-axis.

2. I connect a Palomar noise diode noise bridge at the SO-239 and inject noise. You can homebrew a noise bridge or absent that can just tune to a relatively clear spot on the band.

3. This software is very easy to use and you will soon learn how to make the initial settings and which ones work best. Can insert markers for example at 300hz and 2700hz . Can select different sample rates etc. If I can use it anyone can.

4. This is a poor mans spectrum analyze. You can adjust your TC2/TC3 LSB and USB trimmer caps and see the immediate effects. A great way to set your Carrier Point. Easy to see and adjust the 3dB roll off points to wherever you want them to be. I dont like mine too low (200hz).

To see a sample sweep go to the files and search under the Repair and Alignment folder and I have placed a sweep of LSB on a TS-830 using Spectrogram.

I believe that you can try and buy the upgraded version if you like this older version.

If you have problem and need help I can provide suggested initial settings. I suspect you can play with this and have it running in no time.

Lot of fun to see your passband and very accurate way to adjust LSB/USB carrier osc if you do not have audio generator and wattmeter to set 3db roll off points.

Terry K9TW

Ok, I am now thinking that issue was never resolved the first time I was messing with this radio in 2009. I have made some measurements. I don't have the 500Hz CW filter installed, so this all may be moot when it is.

1. Listening to the 25kHz calibration carrier in SSB gives me some unexpected results. The passband of this radio is VERY wide. It sounds beautiful with the local rag chew groups that are running hi-fi sound. The passband is almost 4kHz wide.

2. Since I don't have the CW filter, my bandwidth is so wide the beat note on the other side of the carrier shows up as I tune through the 25kHz calibration carrier. I have uploaded a you tube video since some folks might not understand what I mean by this, and I want to make sure I am very clear about what is going on here. Here is the video:

http://youtu.be/Ate02ICbLmw

3. I am thinking that this might be a defective multipole crystal passband filter. It sounds beautiful on SSB, but so wide I am hearing a note on both sides of the carrier. This problem will probably be moot when I install the CW filter, but I am thinking I still might not want to be running so wide on SSB.

4. Now I fully remember all the problems I was having with this radio back in 2009, and I still want to keep her and fix her. I now have the biggest problem with the radio behind me, so moving on to this conundrum.

Chris:

OK using the receiver is an acceptable alternative method to adjust carrier suppression. Done it myself lots of times. If you cannot hear carrier on your bench with test receiver then not very likely a fellow hundreds of miles away will.

OK for starters you might want to make sure you have Zero dc volts at the BM terminal on Gen Board in CW mode with Car Pot turned full CCW.

Even though a germanium diode has theoretical barrier potential of approx 0.25vdc (where you will see milliamperes of forward current), below that level you can see ua leakage current down in the .10 to .20 vdc range. Not unusual to see couple hundred ua at that voltage level.

So I think first place to look is at BM to make sure you have Zero vdc with Car at full CCW position.

Terry K9TW

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

On Wed, Sep 18, 2013 at 11:47 AM, <wagstw46@...> wrote:

You can adjust the BM trimmer pot and trimmer cap all day long and the Carrier Osc will never see it. There is a nice buffer stage in the way of that.

Thanks, that rules that cause out.

You cannot just adjust the trimmer pot and trimmer cap on one side band. Has to be done on both and it will be a compromise. Some call this adjusting the Carrier Suppression and

others call it Carrier Balance. It is a back and forth iteration that takes multiple passes to get the carrier nulled equally low on each side band.

SSB is perfect. Problem is just in CW receive.

I usually do it in SSB mode with Mic gain turned down full CCW. Can load to full output power in CW and then switch to SSB and adjust.

Need to connect RF probe/VTVM at SO-239 and key mic or flip to send and adjust for a null in rf voltage on one side band and then flip to other and null again. Will find the trimmers interact and you have to off set and compromise for the best low rf voltage level flipping back and forth between LSB and USB. Will never get it to be zero on both side bands.

I use my FT-817 with no antenna for this. However, per my statement above. I balanced the carrier on Monday the day I replaced the diodes. I am getting a beat note on both sides of the carrier on CW receive only. I remember the cure for this one is to adjust TC1 on the CAR board. Then GEN board is all good. What I was trying to determine is if it is common for the CAR oscillator to drift. Because I am almost 100% certain that the CW receive was good until late last night. I had the radio on all day yesterday, and I was wondering if being turned on for a long time after not being used could cause the carrier osc to drift. I also vaguely remember wanting to replace the 3395.0 Xtal in 2009 because i could not get it to swing all the way to the spec frequency with TC1. However, when I fired it up after sitting for four years last week, I the CW receive was working correctly. Last! night it seemed to have drifted off again. I am thinking I might have to either change the cap our Xtal out. What do you think? I had purchased a very nice frequency counter in 2009 for this project, and was reading the freq straight off of the CAR jack in the back. I think I remember not being able to get it to hit the spec freq.

Terry K9TW

Chris Maness

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

No my assertation was not that scientific. Before I made my fix it was working fine. However, now I am hearing CW on both sides of the carrier. However, as I am composing this I am realizing that changing the capacitor on the balanced mod! ulator might have slightly effected (or pulled) the frequency of the carrier crystal. In that case I just need to readjust and be done with it.

Thanks,
Chris Maness

On Wed, Sep 18, 2013 at 9:56 AM, <wagstw46@...> wrote:

How do you know the Carrier Osc frequency is drifting? Are you watching the Carrier Osc frequency at the CAR term post at the Gen Board with a stable Freq Counter?

Could it be the bal trim pot VR-1 and bal trim cap TC-1 on the Balanced Mod are dirty? Ceramic trim caps are very touchy even from moving the rig around on the bench.

Terry K9TW

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

I purchased it from the Salvation Army back in 2009, and the previous owner went SK in 1995 (from the S.S. number on the rig). So I think it is safe to assume my TS-520S has not been on very much in the past twenty years at least. My experience has taught me that it is not good for a rig to sit idle for years on end. Monday I was finally able to get this radio going 100% with a bad diode on the balanced mixer. Since fixing it, I have been using it a lot, and it seems that the CARRIER has shifted frequencies again. I had adjusted this back in 2009, but last night I was hearing CW notes on both sides of the carrier AGAIN. I guess carrier oscillator has gone squirrely due to running it so much the last few days. However, there are only two parts that control the frequency. The crystal or the trimmer cap. Is it possible that one of these parts have not aged well. I am hopping it will settle down.! ! ;Yesterday I ordered a! CW filter for the radio, should I wait tell this comes before I adjust the CW carrier against the xtal filter skirt or adjust it now and expect that it will fall in line with the new CW filter. The USB/LSB is fine, so I know those two rocks are ok. I only hear a beat note on one side of the carrier in the SSB modes. Should I replace either the trimmer or the Xtal if it keeps drifting around?

Watcha think?

Thanks,
Chris Maness

Yes, I have a Palomar noise bridge. I can do the above setup. Did you watch the video I posted? I used a carrier on my FT-817 to measure the passband by sweeping it, and I came up with the width of the spec stock SSB filter. I could also sweep it and sent the audio to my freq counter. I am not worried about the precision so much as a qualitative test to find out if my SSB crystal filter has gone wide. The TC2/TC3 trimmers are set within spec. I measured them, so the only issue would be if the center freq. of the crystal filter has shifted (I don''t believe it has) or it is REALLY wide. 4kHz seems excessive to me. Was there a super wide crystal filter option for this radio? Maybe the PO was an audio nut and wanted HiFi sound from his TS-520s :D

Thanks,

I have uploaded a you tube video since some folks might not understand what I mean by this, and I want to make sure I am very clear about what is going on here. Here is the video:

http://youtu.be/Ate02ICbLmw

3. I am thinking that this might be a defective multipole crystal passband filter. It sounds beautiful on SSB, but so wide I am hearing a note on both sides of the carrier. This problem will probably be moot when I install the CW filter, but I am thinking I still might not want to be running so wide on SSB.

4. Now I fully remember all the problems I was having with this radio back in 2009, and I still want to keep her and fix her. I now have the biggest problem with the radio behind me, so moving on to this conundrum.

OK using the receiver is an acceptable alternative method to adjust carrier suppression. Done it myself lots of times. If you cannot hear carrier on your bench with test receiver then not very likely a fellow hundreds of miles away will.

OK for starters you might want to make sure you have Zero dc volts at the BM terminal on Gen Board in CW mode with Car Pot turned full CCW.

Even though a germanium diode has theoretical barrier potential of approx 0.25vdc (where you will see milliamperes of forward current), below that level you can see ua leakage current down in the .10 to .20 vdc range. Not unusual to see couple hundred ua at that voltage level.

So I think first place to look is at BM to make sure you have Zero vdc with Car at full CCW position.

Thanks, that rules that cause out.

You cannot just adjust the trimmer pot and trimmer cap on one side band. Has to be done on both and it will be a compromise. Some call this adjusting the Carrier Suppression and others call it Carrier Balance. It is a back and forth iteration that takes multiple passes to get the carrier nulled equally low on each side band.

SSB is perfect. Problem is just in CW receive.

I usually do it in SSB mode with Mic gain turned down full CCW. Can load to full output power in CW and then switch to SSB and adjust.

Need to connect RF probe/VTVM at SO-239 and key mic or flip to send and adjust for a null in rf voltage on one side band and then flip to other and null again. Will find the trimmers interact and you have to off set and compromise for the best low rf voltage level flipping back and forth between LSB and USB. Will never get it to be zero on both side bands.

I use my FT-817 with no antenna for this. However, per my statement above. I balanced the carrier on Monday the day I replaced the diodes. I am getting a beat note on both sides of the carrier on CW receive only. I remember the cure for this one is to adjust TC1 on the CAR board. Then GEN board is all good. What I was trying to determine is if it is common for the CAR oscillator to drift. Because I am almost 100% certain that the CW receive was good until late last night. I had the radio on all day yesterday, and I was wondering if being turned on for a long time after not being used could cause the carrier osc to drift. I also vaguely remember wanting to replace the 3395.0 Xtal in 2009 because i could not get it to swing all the way to the spec frequency with TC1. However, when I fired it up after sitting for four years last week, I the CW receive was working correctly. Last! night it seemed to have drifted off again. I am thinking I might have to either change the cap our Xtal out. What do you think? I had purchased a very nice frequency counter in 2009 for this project, and was reading the freq straight off of the CAR jack in the back. I think I remember not being able to get it to hit the spec freq.

No it would not let me access it.

There is no setting of TC2/TC3 to spec?

You initially set them to the xtal frequency noted in the service manual or on the block diagram to get them in the ball park so the rig will work. However, you are not done yet.

I know of three common ways to set them (bring the oscillators to the xtal filter actual center frequency)

1. Use the Marker/S-meter method. It is described in the TS830 survival guide under the maintenance section and works pretty well. Must do in AGC fast and lite touch on the VFO knob after a good warm up period. Must understand what zero beat is and looks like on an S-meter (slow rythmic needle quiver or swing)

2. Use Audio Generator and RF Wattmeter and set for equal 3 dB roll off. Accurate and easy if you have the test gear.

3. Use Audio Spectrum Analyzer software and set for equal 3 dB roll off. Easy and no test gear required.

These three methods are all within budget for average ham. Of course the new Rigol DSA815-TG Spectrum analyzer is now available for the serious hobbyist. I am hoping for Xmas present.

I am not aware of any KW hybrid filter with 4khz BW. I have seen one bad filter and others on the forum report they have had bad ones. Sometimes very weak output or sometimes OK on one side band and not the other.

Yes, I have a Palomar noise bridge. I can do the above setup. Did you watch the video I posted? I used a carrier on my FT-817 to measure the passband by sweeping it, and I came up with the width of the spec stock SSB filter. I could also sweep it and sent the audio to my freq counter. I am not worried about the precision so much as a qualitative test to find out if my SSB crystal filter has gone wide. The TC2/TC3 trimmers are set within spec. I measured them, so the only issue would be if the center freq. of the crystal filter has shifted (I don''t believe it has) or it is REALLY wide. 4kHz seems excessive to me. Was there a super wide crystal filter option for this radio? Maybe the PO was an audio nut and wanted HiFi sound from his TS-520s :D

If you want to very easily see and measure and adjust your passband response:

Go here and download Spectrogram Version 5.17 Audio Spectrum Analyzer Software to your laptop.

http://w5big.com/spectrogram.htm.

1. Make a patch cord for your headphone jack to the mic/line input to your sound card. I bought a Radio Shack cord with 1/4 inch phone plug on one end and mini-plug on the other end. I cut it in half and installed a log taper audio pot in series to use as a padder. Allows me to set the input level to my sound card to give approx 35 db peak so I dont overload the sound card. You will see dB displayed on the X-axis and frequency on the Y-axis. If you set the gain to your sound card too high the display will start to lift off the Y-axis.

2. I connect a Palomar noise diode noise bridge at the SO-239 and inject noise. You can homebrew a noise bridge or absent that can just tune to a relatively clear spot on the band.

3. This software is very easy to use and you will soon learn how to make the initial settings and which ones work best. Can insert markers for example at 300hz and 2700hz . Can select different sample rates etc. If I can use it anyone can.

4. This is a poor mans spectrum analyze. You can adjust your TC2/TC3 LSB and USB trimmer caps and see the immediate effects. A great way to set your Carrier Point. Easy to see and adjust the 3dB roll off points to wherever you want them to be. I dont like mine too low (200hz).

To see a sample sweep go to the files and search under the Repair and Alignment folder and I have placed a sweep of LSB on a TS-830 using Spectrogram.

I believe that you can try and buy the upgraded version if you like this older version.

If you have problem and need help I can provide suggested initial settings. I suspect you can play with this and have it running in no time.

Lot of fun to see your passband and very accurate way to adjust LSB/USB carrier osc if you do not have audio generator and wattmeter to set 3db roll off points.

OK what you are doing is very imprecise. Using a yard stick.

Here is what I would do:

1. Rig on dummy load or no antenna
2. Turn AGC on to Fast.
3. Set VFO to 200
4. Mode in LSB. Tune the VFO for zero beat. As you approach zero beat use light touch or tap on the VFO knob. Should see see rythmic needle quiver at approx S3.
5. Set your analog dial to zero. Tap on VFO dial to get a slow rythmic quiver. Dont stop it. Want some quiver to make sure close to zero beat.
6. Very slowly move the VFO dial and watch the analog divisions and the S-meter. As you get close to approx 2.5 divisions the S-meter should fall to zero. You may still hear very high pitched note.
7. Repeat on USB. Should get zero beat near S3. Should see S-meter fall off near 2.5 divisions. It could be 2.4 it could be 2.7 but you are using a yard stick to measure with.
8. Now set to CW mode.
9. Slowly adjust VFO for zero beat. This time it should occur closer to S5 to S6. Set analog dial to zero.
10. Move VFO dial up frequency and watch analog dial and S-meter. Should see S-meter fall to zero at approx 2 divisions. Return to zero beat.
11. Move VFO dial down frequency and watch analog dial and S-meter. Should see S-meter fall to zero in just slightly less than 1 division. If you keep turning you will hear more signal. Ignore that. You are using a harmomic rich signal source.

So in CW you dont have 4khz bandwidth. Using Marker and S-meter and Fast AGC and good touch on VFO dial you will see S-meter fall to zero at approx 3khz and it is really 2.7 or so if you were measuring it. .

The reason in CW mode that you will see close to 2 divisions on one side and 1 division on the other is that the filter response is not completely symmetrical. If you download the Spectrogram software or look at the sample I placed in the files you will see this.

For purposes of this test only.

My LSB osc was set at 3393,621 mhz
My USB osc was set at 3396.356 mhz
My CWR was set at 3394.319 mhz
CWT went up appropriate 700hz

Th LSB and USB osc were set using the Marker S meter method. Background noise as a switch from LSB to USB sounds close to my ear.

However, I now need to go back and set with Spectrogram or Audio Gen and Wattmeter. I suspect will be close but need some tweaking.

I just set them to get approx S3 zero beat so could duplicate what you are trying to do.

I forgot to mention when I speak about 3dB roll off I am talking about RF power using the wattmeter method.

If you use Spectrogram you will measure the BW at 6dB points on each side of the displayed response curve.

All you have to do move cursor along the curve and it will display when you are at 6dB down and you can place a marker there if you chose or just read the frequency displayed in the box and log it down.

Wes,

I do not know the history of your DG-5 so I am going to assume it is "unknown" and you are working on it for the first time. Do you have a schematic for the DG-5? If not, you will need one. I believe you already have the manual and schematic for the '520SE.

I would start troubleshooting by measuring the voltage and polarity of the DG-5 socket on the back of the '520SE to eliminate it as a source of the problem. Once I knew that was good I would check the wiring of the DG-5 connectors and the wiring to make sure it was the correct polarity (to mate with the '520SE) and that it wasn't shorted.

Diode D18 in the DG-5 is wired for reverse voltage protection. If it is shorted, or the voltage polarity from the '520SE is incorrect, it will cause the symptoms you are seeing. It is unlikely that the 0.01 cap across the DG-5 power input is shorted but it can't be ruled out in an "unknown" device.

The voltage regulators, FS7805 and Q31(w/Zener D17), as well as the power transistor, 2SD235, would be the next items to check since they feed power to the rest of the circuitry. You should also check for a short in capacitor C88 (47uf/25V) on the input to the FS7805 and C86 (22uf/16V) on the emitter of the 2SD235 transistor.

Assuming the above devices are not shorted then I would set the DG-5 to "COUNTER" mode and connect it to a current-limited bench power supply and slowly crank up the voltage while watching the mA meter and the front panel display of the DG-5. You are looking to see if it only draws significant current when powered up vs a hard short that can be found with the power off. The DG-5 specs indicate 0.9A (900mA) max so you want to see is if there is a significant current draw as you increase the voltage. It should stabilize below 900mA and the display should show signs of life. Of course, there should be no snap, crackle, and/or pop nor the dreaded release of factory smoke!

Keep us posted on your progress!

It is, but it got 2.8kHz for my FT-817. The spec is 2.3kHz not too far
off. I am just saying that 4kHz seems REALLY wide as unscientific and
qualitative as a test as it is.

Topic: 44729 Message: 44729

I uploaded 2 new videos this afternoon. They are in the "Grid Voltage"
folder(see the following links)

http://www.n6wk.com/w5rkl/Grid%20Voltage/Grid%20voltage%20changes%20based%20on%20sine%20wave%20voltage%20levels%20part%202.wmv

and

http://www.n6wk.com/w5rkl/Grid%20Voltage/Grid%20voltage%20changes%20causes%20changed%20in%20tubes%20plate%20voltage%20drop%20and%20plate%20voltage.wmv

I recommend reviewing part 1 again, then part 2 and finally the last
video discussing grid voltage changes affecting the plate voltage drop
and plate voltage. All 3 videos gotogether.

Steve,

I think this question was asked a few days ago..or maybe longer...can't remember.

I my humble opinion..you are NOT going to see any real operational difference...same goes for "matched pairs" of 6146's....not necessary
Just make sure that since you replaced the finals that you "neutralize" them. Directions are in the "operators" & "service manuals."

I recently replaced my finals in my Kenwood TS820 with a set of NOS 6146B's. They have the black plates. Is there an advantage to the black plates or should I have used the grey plate version?

I appreciate the explanations. I have gone over it and it appears the mod was started but never finished. The switch is installed but the wire has not been cut. I removed it and put the wire back in the molex connector and all receive and transmit are working fine. I was lucky there was not more damage. I understand what they were in the process of doing now. The molex connector is melted around the pin hole and will need replaced. It appears someone was actually trying to desolder? the wire right in the connector. I have a few spares. I will recheck the PLL board to make sure I did not miss anything. Just need a cw filter and it will look good on my station console. Thanks Terry and Joe. I put it in my notes.

I acquired a TS 530SP with an on/off switch wired into the counter board on connector #2 pin #9. Rather hacked at that. I removed it and reconnected wire to the connector and receive works fine on the affected bands. The owner had stated that it would not receive and readout was blank so he evidently did not do the mod. He is a Ham up north and was only interested in getting rid of it. It is in relatively good shape and has a 6 million serial no.and still has the KW inspection stickers inside dated 1989, so I think I may hold on to this rig but this is the second time I have run into this mod and do not know what benefit it could be. The other time was in a TS 830 several years ago. Same scenario. I know I do not get out much but I can not figure out what this would do other than shut down several bands. Why would you do that? I am getting to the point of not being surprised by any of the hack jobs but if someone has an opinion about this let me know. Wouldn't you just like to smack someone if you caught them?

Don,

u r welcome. You were lucky...I've seen some real butcher jobs. What seems to get the most damage..besides the wiring/connectors...etc.
is the components in the final compartment, mainly the plate choke...it should look kinda bright...not brown/black...also the cathode resistors
on the final board also take a beating by persons doing these mods...including the "QRO MOD," which I've also seen go with the "CB HACK."
Glad it was easy to get it back in operation.....

Subject: [TS-520_820_530_830] Is anyone else getting board messages out of order?

For instance, Lars' message around 0730-ish this morning just arrived,
which made the reply I received in near-real-time from Terry (some time
after 0800) make a lot more sense.

Those two aren't the only messages which have come in to my in-box today
in reverse or otherwise scrambled order. Several threads are pied like
that so far.

Is there some blockage in the system? Does Yahoo hate me for denying
them the opportunities for more Spam in my in-box, or is it simply that
I'm a Luddite when it comes to this stuff, preferring that text messages
be TEXT messages without a lot of fluff on top?

I do not ever use the web page interface, I find such things to be
excessively loaded with "features" which I never need, want, nor use.

I just read email. Words in a row. I like it that way.

I have seen references to "the changes" to "the system," which I am
assuming mean something to do with the way the Yahoo web site for forae
like this one is set up. Is this related? Just started in the last day
or so,

My own MailMan mailing list server (sits in the rack in the basement,
just runs, has done so for years) and Postfix SMTP and Dovecot IMAP
set-up doesn't deliver mail backwards through time; or if it does none
of the folks using it have ever mentioned it to me. Since none of my
systems have been down at all, I am at a loss to understand how this
recent phenomenon could occur without positing some sort of error at Yahoo.

Any Clues? Or is it just me?

Subject: [TS-520_820_530_830] TS-520S Passband Problems WAS: CARRIER instability on the TS-520S

Ok, I am now thinking that issue was never resolved the first time I was messing with this radio in 2009. I have made some measurements. I don't have the 500Hz CW filter installed, so this all may be moot when it is.

1. Listening to the 25kHz calibration carrier in SSB gives me some unexpected results. The passband of this radio is VERY wide. It sounds beautiful with the local rag chew groups that are running hi-fi sound. The passband is almost 4kHz wide.

2. Since I don't have the CW filter, my bandwidth is so wide the beat note on the other side of the carrier shows up as I tune through the 25kHz calibration carrier. I have uploaded a you tube video since some folks might not understand what I mean by this, and I want to make sure I am very clear about what is going on here. Here is the video:

http://youtu.be/Ate02ICbLmw

3. I am thinking that this might be a defective multipole crystal passband filter. It sounds beautiful on SSB, but so wide I am hearing a note on both sides of the carrier. This problem will probably be moot when I install the CW filter, but I am thinking I still might not want to be running so wide on SSB.

4. Now I fully remember all the problems I was having with this radio back in 2009, and I still want to keep her and fix her. I now have the biggest problem with the radio behind me, so moving on to this conundrum.

>>>
>>>
>>I use my FT-817 with no antenna for this. However, per my statement above. I balanced the carrier on Monday the day I replaced the diodes. I am getting a beat note on both sides of the carrier on CW receive only. I remember the cure for this one is to adjust TC1 on the CAR board. Then GEN board is all good. What I was trying to determine is if it is common for the CAR oscillator to drift. Because I am almost 100% certain that the CW receive was good until late last night. I had the radio on all day yesterday, and I was wondering if being turned on for a long time after not being used could cause the carrier osc to drift. I also vaguely remember wanting to replace the 3395.0 Xtal in 2009 because i could not get it to swing all the way to the spec frequency with TC1. However, when I fired it up after sitting for four years last week, I the CW receive was working correctly. Last! night it seemed to have drifted off again. I am
thinking I might have to either change the cap our Xtal out. What do you think? I had purchased a very nice frequency counter in 2009 for this project, and was reading the freq straight off of the CAR jack in the back. I think I remember not being able to get it to hit the spec freq.

So I think it is safe to assume my TS-520S has not been on very much in the past twenty years at least. My experience has taught me that it is not good for a rig to sit idle for years on end. Monday I was finally able to get this radio going 100% with a bad diode on the balanced mixer. Since fixing it, I have been using it a lot, and it seems that the CARRIER has shifted frequencies again. I had adjusted this back in 2009, but last night I was hearing CW notes on both sides of the carrier AGAIN. I guess carrier oscillator has gone squirrely due to running it so much the last few days. However, there are only two parts that control the frequency. The crystal or the trimmer cap. Is it possible that one of these parts have not aged well. I am hopping it will settle down.! ?! ;Yesterday I ordered a! CW
filter for the radio, should I wait tell this comes before I adjust the CW carrier against the xtal filter skirt or adjust it now and expect that it will fall in line with the new CW filter. The USB/LSB is fine, so I know those two rocks are ok. I only hear a beat note on one side of the carrier in the SSB modes. Should I replace either the trimmer or the Xtal if it keeps drifting around?

44735. Short in my TS-520S

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-20 00:43:25 UTC
From: Chris Maness
Topic: 44735 Message: 44735

I just installed my CW filter in my radio, and turned it on to find out now it has a short. I almost cried. Perfect clean solder joints on the IF board. I didn't drop any screws in the works, but it is blowing the 2A side. The meter light comes on, and the filaments, but everything else is dead. I have no idea what happened. Maybe putting stress on the wire harness to flip the board out to work on it might have done something. Maybe the wire underneath the filter got mashed and shorted against the filter case. I will check that option.

Pinch a wire under the Board when re-installing?

44738. What does Voltage Drop mean video

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)

Topic: 44738 Message: 44738

I uploaded a video in the Ohms Law test folder explaining, with explanation, what the term Voltage Drop means. This is another term that you should know what it means so you will understand what is being said when the term is used.

Yes, I now how the CW filter inline, and the double sided carrier note is gone, as I figured it would. Terry, I will take some time and do a more quantitative measurement on the SSB passband. The CW passband is now to my liking. So do most of the TS-520S without the filter have beat note on both sides?

Thanks,
73's de KQ6UP

Thanks Joe.

I'm new here as I just got the 820 not too long ago. I did a search but could not find the topic.
I have heard that the black plate tubes have a deeper less hollow sound but that was for guitar amplifiers.
I guess that for ham radio and especially SSB, the final tubes are not as particular as far as sound goes.

Thanks again. 73....N8WGM

If i remember correctly they were equivalents to the 3SK45. Under a different number though, fortunately the Auckland VHF group trading table had some.
Their noise performance looked quite good.

44744. Tuned the 520SE up on all bands.

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-20 04:20:30 UTC
From: Wes Will
Topic: 44735 Message: 44744

Full 100W on 80, 40, and 20. About 85W on 160, and a bit less than 80W above 20 meters. That's with the plate current kept at or just above 100 mA. No higher than 110 mA, though.

Used an external Wattmeter, tuned it the hard way using the long-form instruction sheet. Will convert my scribbled notes on switch positions into something legible very shortly.

Tuned into my homemade can of mineral oil and resistors. Don't have an antenna yet, but will probably toss something into the trees to get going with. Suggestions there would be welcome, I'm always up for a rag-chew about antennas.

Took a few tries to remember how that all went, but once I started remembering and seeing the dip and peak while adjusting the controls, well, it sort of all came back.

Couple of things I noticed:

1) On receive, all bands, there is an awful lot of white noise. Even on a can full of resistors on a quarter-meter long coax stub. Clean, perfectly regular and "smooth" white noise.

2) The plate control setting was nowhere NEAR the dialed-in band. For 20 meters, for instance the indicator was closer to 7 MHz than 14. How worried should I be?

Should I look at doing a coil pack alignment, or should I just look at them and see if any are bottomed out?

I suspect the driver tube is starting to flake out, but right now it's fine. I'll let it ride and get some hours on the thing. If it's dying it will show itself under use fairly quickly, I suspect.

Finals seem great. Checked inside the cage and the resistors look good, and the coils are still nice and bright; nothing blackened or toasted.

The silly little plastic switch tab on the send/receive toggle is loose, feels like it's going to come out like a bad tooth under my fingers. What's the word on fixing those switches (all of them) so they don't flop around and feel like they're going to come off in your hand when you touch one? It seems to be just long usage, not abuse or anything really broken. (I just like a firm response to a control. Maybe it's just a quirk of mine but I don't like sloppy controls.)

I stuck a length of wire on the antenna plug, and started hearing some strong signals from various places around the country. I'm in 9-land, I heard a couple of 5's and a 0 call sign. I need better headphones,

couldn't get tuned in over the white noise quickly enough to get the call signs, (I couldn't spend much time hunting, either. In the middle of making dinner, had to go cook some pork steak and squash and sprouts.)

So, other than a bit noisier than I think it ought to be, and perhaps something odd with the output Pi section, it's working.

One more question. While I have this thing open and belly up on the bench, which voltage measurements would be the most sensible to take NOW while it's working, so that later when it isn't I'll have baseline data? I've written some measurements down, but having all of the important ones in my notebook (and not missing any from being inexperienced with these rigs) would make me feel a lot better about putting the lid on this beast tomorrow.

Thanks for bearing with me, all. You're a great bunch, and a fantastic resource. I am appreciative.

Wes

Using the external wattmeter is not the "long or hard" way to load?

Very simple simple procedure. Peak the Drive in Tune. Get the initial plate current dip in Tune (done for safety in case the tank has not been preset close to resonance and would have excessively high plate current). Leave meter in Ip. Switch to CW mode. Flip to Send. Alternately adjust Plate Load and Plate Tune caps for approx 100 watts output into dummy load (there is no dip and load involved) . Verify not exceeding approx 200 ma. Unkey the rig. Your done in matter of seconds.

Very easy to learn and perform, faster method, and less stress on the finals, and you can immediately tell if something is wrong by looking at output level on the wattmeter.

For example, if you have an open in your feed line anywhere you can load normally by plate current or RF relative power meter method and not notice you have a problem unless you are very experienced. With the wattmeter method you will see ZERO output yet will see 100ma plus Ip. This should immediately tell you something is wrong. Never want to load into an open with a TS520 as the rig doesn not have RF negative feedback like the later rigs and the very high VSWR results in high rf voltage at your SO-239 connector which appear across the plates of your Plate Load capacitor. At approx 100ma IP you will have just over 200 rf volts. This is a close spaced broadcast type air variable and easy to arc it over. So an external wattmeter is a great loading aid as gives you an approx value to shoot for and immediate indication when there is a problem with your antenna system. Opens, shorts, high resistance, balun breaking down etc. will all manifest themselves on your wattmeter.

Once you get use to this method it can be done in seconds. It is the method described in your manual accept they tell you to use the built in RF relative power position. Adding a wattmeter puts a real number to that method.

Also. it is not possible to get 100 watts output at 100ma plate current. If this is not a typo then you need to verify the accuracy of your external wattmeter.

Assuming 825vdc plate voltage then 825 x .100 = 82.5 watts dc input power. Assuming 55% efficiency then 82.5 x .55 = 45 rf watts output into your dummy load. Absolute best condition would be something on order of 840 x .100 = 84 watts input X .60 = 50 Watts output. At 100ma best you should see on wattmeter into 50 ohm dummy load is 50 watts.

The way you can check the accuracy of your wattmeter is to measure the RF voltage drop across the 50 ohm resistors with a RF probe and VTVM/DMM.

At 100 watts output you will have approx 70.7 rms rf volts.

70.7 x 70.7 /50 = 4998/50 = 99.96 watts

Need a 3 diode RF probe or an O-scope to make this measurement. Place a coaxial Tee at the dummy load and measure IR drop at the open end of the Tee.

If using an O-scope will read 70.7 X 2.828 = 200 volts P-P.

If you actually have something on the order of 840 vdc and 100 ma and resulting 50 watt rf output then the voltage at the open Tee will be approx 50 rms rf volts or 141v P-P.

Chris:

I obviously do not believe that you have a stock SSB xtal filter that has a -6dB band width of 4 khz. The spec is -6dB BW = 2400hz and -60dB BW = 4.4khz.

I do not believe you have 4 khz BW at -6dB and I do not have 3khz BW at -6dB. We are looking at the limitations of the accuracy of our Marker/S-meter measuring method.

If you sweep your filter with accurate method and find otherwise I will offer public apology and I owe you a beer to two!

The point of my note was to help you refine your Marker method to get a result closer to 3khz.

Only way you accurately measure the -6dB BW of your SSB filter is:
1. Sweep it with a standard RF sweep generator and view on calibrated O-scope using KW markers.
2. Sweep it with a RF Spectrum Analyzer and Tracking Generator.
3. Sweep it with a 2 port VNA (Couple of nice USB models now available in the $500 range)
4. Sweep it with Spectrogram Audio Spectrum Analyzer software and noise bridge. (cheapest method)

After I ran the Marker/S-meter method and got my approx 3khz result I decided to take a look with Spectrogram. Had been awhile and I needed to re-set the LSB/USB trimmers back to the SSB response I like.

I left TC-2/TC-3 as left after the Marker/Smeter measurement method and ran Spectrogram. I found the -6dB BW to be very close to 2.4khz but the low end was at approx 450 hz so I adjusted the trimmers to lower it to 300hz. Also, my balance between LSB and USB was off a little with USB being shifted higher.

I try to set mine for more SSB communications audio and not bass response that everyone seems to favor. I want little ,more high end presence as I run barefoot.

Subject: [TS-520_820_530_830] TS-520S Passband Problems WAS: CARRIER instability on the TS-520S

Ok, I am now thinking that issue was never resolved the first time I was messing with this radio in 2009. I have made some measurements. I don't have the 500Hz CW filter installed, so this all may be moot when it is.

1. Listening to the 25kHz calibration carrier in SSB gives me some unexpected results. The passband of this radio is VERY wide. It sounds beautiful with the local rag chew groups that are running hi-fi sound. The passband is almost 4kHz wide.

2. Since I don't have the CW filter, my bandwidth is so wide the beat note on the other side of the carrier shows up as I tune through the 25kHz calibration carrier. I have uploaded a you tube video since some folks might not understand what I mean by this, and I want to make sure I am very clear about what is going on here. Here is the video:

http://youtu.be/Ate02ICbLmw

3. I am thinking that this might be a defective multipole crystal passband filter. It sounds beautiful on SSB, but so wide I am hearing a note on both sides of the carrier. This problem will probably be moot when I install the CW filter, but I am thinking I still might not want to be running so wide on SSB.

4. Now I fully remember all the problems I was having with this radio back in 2009, and I still want to keep her and fix her. I now have the biggest problem with the radio behind me, so moving on to this conundrum.

Chris:

OK using the receiver is an acceptable alternative method to adjust carrier suppression. Done it myself lots of times. If you cannot hear carrier on your bench with test receiver then not very likely a fellow hundreds of miles away will.

OK for starters you might want to make sure you have Zero dc volts at the BM terminal on Gen Board in CW mode with Car Pot turned full CCW.

Even though a germanium diode has theoretical barrier potential of approx 0.25vdc (where you will see milliamperes of forward current), below that level you can see ua leakage current down in the .10 to .20 vdc range. Not unusual to see couple hundred ua at that voltage level.

So I think first place to look is at BM to make sure you have Zero vdc with Car at full CCW position.

On Wed, Sep 18, 2013 at 11:47 AM, <wagstw46@...> wrote:

You can adjust the BM trimmer pot and trimmer cap all day long and the Carrier Osc will never see it. There is a nice buffer stage in the way of that.

Thanks, that rules that cause out.

You cannot just adjust the trimmer pot and trimmer cap on one side band. Has to be done on both and it will be a compromise. Some call this adjusting the Carrier Suppression and others call it Carrier Balance. It is a back and forth iteration that takes multiple passes to get the carrier nulled equally low on each side band.

SSB is perfect. Problem is just in CW receive.

I usually do it in SSB mode with Mic gain turned down full CCW. Can load to full output power in CW and then switch to SSB and adjust.

Need to connect RF probe/VTVM at SO-239 and key mic or flip to send and adjust for a null in rf voltage on one side band and then flip to other and null again. Will find the trimmers interact and you have to off set and compromise for the best low rf voltage level flipping back and forth between LSB and USB. Will never get it to be zero on both side bands.

I use my FT-817 with no antenna for this. However, per my statement above. I balanced the carrier on Monday the day I replaced the diodes. I am getting a beat note on both sides of the carrier on CW receive only. I remember the cure for this one is to adjust TC1 on the CAR board. Then GEN board is all good. What I was trying to determine is if it is common for the CAR oscillator to drift. Because I am almost 100% certain that the CW receive was good until late last night. I had the radio on all day yesterday, and I was wondering if being turned on for a long time after not being used could cause the carrier osc to drift. I also vaguely remember wanting to replace the 3395.0 Xtal in 2009 because i could not get it to swing all the way to the spec frequency with TC1. However, when I fired it up after sitting for four years last week, I the CW receive was working correctly. Last! night it seemed to have drifted off again. I am thinking I might have to either change the cap our Xtal out. What do you think? I had purchased a very nice frequency counter in 2009 for this project, and was reading the freq straight off of the CAR jack in the back. I think I remember not being able to get it to hit the spec freq.

No my assertation was not that scientific. Before I made my fix it was working fine. However, now I am hearing CW on both sides of the carrier. However, as I am composing this I am realizing that changing the capacitor on the balanced mod! ulator might have slightly effected (or pulled) the frequency of the carrier crystal. In that case I just need to readjust and be done with it.

Thanks,
Chris Maness

On Wed, Sep 18, 2013 at 9:56 AM, <wagstw46@...> wrote:

How do you know the Carrier Osc frequency is drifting? Are you watching the Carrier Osc frequency at the CAR term post at the Gen Board with a stable Freq Counter?

Could it be the bal trim pot VR-1 and bal trim cap TC-1 on the Balanced Mod are dirty? Ceramic trim caps are very touchy even from moving the rig around on the bench.

Terry K9TW

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

I purchased it from the Salvation Army back in 2009, and the previous owner went SK in 1995 (from the S.S. number on the rig). So I think it is safe to assume my TS-520S has not been on very much in the past twenty years at least. My experience has taught me that it is not good for a rig to sit idle for years on end. Monday I was finally able to get this radio going 100% with a bad diode on the balanced mixer. Since fixing it, I have been using it a lot, and it seems that the CARRIER has shifted frequencies again. I had adjusted this back in 2009, but last night I was hearing CW notes on both sides of the carrier AGAIN. I guess carrier oscillator has gone squirrely due to running it so much the last few days. However, there are only two parts that control the frequency. The crystal or the trimmer cap. Is it possible that one of these parts have not aged well. I am hopping it will settle down.! ! ;Yesterday I ordered a! CW filter for the radio, should I wait tell this comes before I adjust the CW carrier against the xtal filter skirt or adjust it now and expect that it will fall in line with the new CW filter. The USB/LSB is fine, so I know those two rocks are ok. I only hear a beat note on one side of the carrier in the SSB modes. Should I replace either the trimmer or the Xtal if it keeps drifting around?

Watcha think?

Thanks,
Chris Maness

After placing the narrow filter in the radio I notice some wide band white noise in the RX. This is wider than the filter skirt. It was there before, but not very noticeable due to the RX noise masking it. It also seems to go up and down proportionally to the AGC. It is not too distracting, but I was wondering if this is normal with this radio.

Thanks,
Chris Maness

OK I should not use the "ONLY" word.

Yes you can sweep the filter with a straight RF sig gen in very small steps and measure the RF output voltage at each frequency step and then plot the points on a graph and produce the filter response curve. Done this many times is the ancient past and a bit tedious, but is another method to reasonably measure the -6dB BW of your IF filter.

I should know better than to use Never or Always or Only or ....!

So I think first place to look is at BM to make sure you have Zero vdc with Car at full CCW position.

You can adjust the BM trimmer pot and trimmer cap all day long and the Carrier Osc will never see it. There is a nice buffer stage in the way of that.

Thanks, that rules that cause out.

You cannot just adjust the trimmer pot and trimmer cap on one side band. Has to be done on both and it will be a compromise. Some call this adjusting the Carrier Suppression and others call it Carrier Balance. It is a back and forth iteration that takes multiple passes to get the carrier nulled equally low on each side band.

SSB is perfect. Problem is just in CW receive.

I usually do it in SSB mode with Mic gain turned down full CCW. Can load to full output power in CW and then switch to SSB and adjust.

Need to connect RF probe/VTVM at SO-239 and key mic or flip to send and adjust for a null in rf voltage on one side band and then flip to other and null again. Will find the trimmers interact and you have to off set and compromise for the best low rf voltage level flipping back and forth between LSB and USB. Will never get it to be zero on both side bands.

I use my FT-817 with no antenna for this. However, per my statement above. I balanced the carrier on Monday the day I replaced the diodes. I am getting a beat note on both sides of the carrier on CW receive only. I remember the cure for this one is to adjust TC1 on the CAR board. Then GEN board is all good. What I was trying to determine is if it is common for the CAR oscillator to drift. Because I am almost 100% certain that the CW receive was good until late last night. I had the radio on all day yesterday, and I was wondering if being turned on for a long time after not being used could cause the carrier osc to drift. I also vaguely remember wanting to replace the 3395.0 Xtal in 2009 because i could not get it to swing all the way to the spec frequency with TC1. However, when I fired it up after sitting for four years last week, I the CW receive was working correctly. Last! night it seemed to have drifted off again. I am thinking I might have to either change the cap our Xtal out. What do you think? I had purchased a very nice frequency counter in 2009 for this

project, and was reading the freq straight off of the CAR jack in the back. I think I remember not being able to get it to hit the spec freq.

Terry K9TW

Thanks,
Chris Maness

No my assertation was not that scientific. Before I made my fix it was working fine. However, now I am hearing CW on both sides of the carrier. However, as I am composing this I am realizing that changing the capacitor on the balanced mod! ulator might have slightly effected (or pulled) the frequency of the carrier crystal. In that case I just need to readjust and be done with it.

Thanks,
Chris Maness

On Wed, Sep 18, 2013 at 9:56 AM, <wagstw46@...> wrote:

How do you know the Carrier Osc frequency is drifting? Are you watching the Carrier Osc frequency at the CAR term post at the Gen Board with a stable Freq Counter?

Could it be the bal trim pot VR-1 and bal trim cap TC-1 on the Balanced Mod are dirty? Ceramic trim caps are very touchy even from moving the rig around on the bench.

Terry K9TW

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

I purchased it from the Salvation Army back in 2009, and the previous owner went SK in 1995 (from the S.S. number on the rig). So I think it is safe to assume my TS-520S has not been on very much in the past twenty years at least. My experience has taught me that it is not good for a rig to sit idle for years on end. Monday I was finally able to get this radio going 100% with a bad diode on the balanced mixer. Since fixing it, I have been using it a lot, and it seems that the CARRIER has shifted frequencies again. I had adjusted this back in 2009, but last night I was hearing CW notes on both sides of the carrier AGAIN. I guess carrier oscillator has gone squirrely due to running it so much the last few days. However, there are only two parts that control the frequency. The crystal or the trimmer cap. Is it possible that one of these parts have not aged well. I am hopping it will settle down.! ! ;Yesterday I ordered a! CW filter for the radio, should I wait tell this comes before I adjust the CW carrier against the xtal filter skirt or adjust it now and expect that it will fall in line with the new CW filter. The USB/LSB is fine, so I know those two rocks are ok. I only hear a beat note on one side of the carrier in the SSB modes. Should I replace either the trimmer or the Xtal if it keeps drifting around?

Watcha think?

Thanks,
Chris Maness

Steve,

I think this question was asked a few days ago..or maybe longer...can't remember.

I my humble opinion..you are NOT going to see any real operational difference...same goes for "matched pairs" of 6146's....not necessary
Just make sure that since you replaced the finals that you "neutralize" them. Directions are in the "operators" & "service manuals."

Ummm.... That's kind of what I said. I used the method in the printed manual, which is the LONG way. Not the SHORTER way using the wattmeter.

And I very much already suspected that the plate current meter was out of calibration. It showed a needle-width above 100ma when the external wattmeter showed 101 watts. I will adjust it post haste.

And I'll look (harder, elsewhere, obviously) for a list of which voltages would be appropriate for me to note down while it is working to aid later troubleshooting. Just using the schematic I'm quite liable to miss some important ones.

Diodes on the way soon.

Turns out the vendor is on holiday somewhere, should be back in the UK and ready to process an order in a few more days.

The lucky stiff. What's a "holiday"??

Anyway, so far I have orders for 40 V06B diodes (10 for me, 24 for Joseph, 6 for Terry - on me, Terry, for the help).

Anyone else for that part, or any of the others on his list? Some fairly rare items in there. Not much longer until they're gone.

Drop a line to me off the list if there is anything you want to add. It will save a lot of shipping, a bunch of small parts weigh less than the envelope they get mailed in. No risks, I'll foot the bill for the order, and will trust list members to PayPal or mail me the couple bucks it will actually cost.

99 pence (UK) per ten, for most items. Add in a bit for a portion of the shipping (the more that order, the less each) and it's around a quarter each for that quantity/price. Around $2.50 for ten diodes, in other words. (Exact amount depends on the actual shipping cost and the number of people to divide it amongst. Two so far.)

I'll eat the currency exchange losses, shouldn't be much.

OK Sorry not what I read or understood. No reason to use the rigs RF position.

Also, you cannot "adjust" the rigs Plate current meter in the sense we normally associate with adjustment. There is no cal trim pot.

Have you checked the two 10 ohm cathode meter shunt resistors? I suggest you replace both for starters. Replace with metal film.

I wonder what would happen if someone installed two 5 ohm resistors? Maybe an example of Mikes parallel resistor primer?

If they check good then check 3.3k meter multiplier resistor. If it checks good then possible to have bad cathode bypass caps but I have never seen one.

You can also measure 6146 cathode voltage key down into dummy load and work the math. With 200 ma and 5 ohm meter shunt what voltage would you expect the cathode to be?

OK Sorry not what I read or understood. No reason to use the rigs RF position.

Also, you cannot "adjust" the rigs Plate current meter in the sense we normally associate with adjustment. There is no cal trim pot.

Have you checked the two 10 ohm cathode meter shunt resistors? I suggest you replace both for starters. Replace with metal film.

I wonder what would happen if someone installed two 5 ohm resistors? Maybe an example of Mikes parallel resistor primer?

If they check good then check 3.3k meter multiplier resistor. If it checks good then possible to have bad cathode bypass caps but I have never seen one.

You can also measure 6146 cathode voltage key down into dummy load and work the math. With 200 ma and 5 ohm meter shunt what voltage would you expect the cathode to be?

> Using the external wattmeter is not the "long or hard" way to load?

Ummm.... That's kind of what I said. I used the method in the printed
manual, which is the LONG way. Not the SHORTER way using the wattmeter.

And I very much already suspected that the plate current meter was out
of calibration. It showed a needle-width above 100ma when the external
wattmeter showed 101 watts. I will adjust it post haste.

And I'll look (harder, elsewhere, obviously) for a list of which
voltages would be appropriate for me to note down while it is working to
aid later troubleshooting. Just using the schematic I'm quite liable to
miss some important ones.

TS 820s tune receive tune up/alignment issue

Need some help; I am having an S-20 to 30 noise level on receive. I have a friend that will help me with the tune up/alignment of the radio and double checking the receive side to determine if that is the source/cause of my noise.
So to those who have experience in the tune/alignment of this radio, any suggestions, things to look for or areas that could be the issue/cause of the noise?
As a side bar, I have tried different antennas and even different houses 200 miles apart, no difference in the noise level in receive.
I have the owner's manual and the service manual.
My sincere thanks to all.

Re final cathode resistors. Yes they are a known source of trouble. Since they were combined in parallel and a bit stressed, it is very common for one to go high and put both of them out. I have replaced mine with a Wirewound 5 watt resistor. However I triple by passed it with 3 different capacitor values and it works fine (and it won't happen again).

I would say the noise is about a 1 with no antenna.

Yes the noise is there with and without the heater.

I can take a video clip with sound if that would help.

Thank you VERY MUCH for trying to help me

Sent: Friday, September 20, 2013 3:01 PM
Subject: [TS-520_820_530_830] V06B diodes - finally heard from the vendor.

Diodes on the way soon.

Turns out the vendor is on holiday somewhere, should be back in the UK
and ready to process an order in a few more days.

The lucky stiff. What's a "holiday"??

Anyway, so far I have orders for 40 V06B diodes (10 for me, 24 for
Joseph, 6 for Terry - on me, Terry, for the help).

Anyone else for that part, or any of the others on his list? Some
fairly rare items in there. Not much longer until they're gone.

Drop a line to me off the list if there is anything you want to add. It
will save a lot of shipping, a bunch of small parts weigh less than the
envelope they get mailed in. No risks, I'll foot the bill for the
order, and will trust list members to PayPal or mail me the couple bucks
it will actually cost.

99 pence (UK) per ten, for most items. Add in a bit for a portion of
the shipping (the more that order, the less each) and it's around a
quarter each for that quantity/price. Around $2.50 for ten diodes, in
other words. (Exact amount depends on the actual shipping cost and the
number of people to divide it amongst. Two so far.)

I'll eat the currency exchange losses, shouldn't be much.

Steve:

I have never replaced a band switch coupler on a TS-820. My personal one still has the original nylon.

With 3500 members you would think someone could help you with this. I cannot be all things to all people. Trying to do that gets me and them in trouble.

I can tell you what I see on my TS820.

This assumes you did not let any of the 6 wafer switches on the coil pack board rotate if you pulled the long shaft out of all of them.

With rig facing you and looking down from the top here is what is see.
1. Band switch at 29mhz
2. The knob driven band switch shaft has 2 flats and they are facing left and right.
3. Coming up to the short stub shaft from the front panel bushing to the white nylon chain drive gear there is 1 flat that is facing to the left.
3. The long coil pack shaft has 2 flats and they are facing to the left and ride side of the rig.
4. The S22 switch in the PA cage has 2 flats and one is facing straight up (1200) and the other is facing the right side (1500) of the rig.

Terry,

Thanks for the quick response, and thanks for going to the trouble of checking your 820 for me. When the front panel band select switch on my unit selects 29mHz the flats are not facing left and right like yours, and that part of the mechanical assemblies has not been changed. I tried aligning the other shafts per your results without success.

Unless others chime in with some alignment advice I plan to try tuning to 15MHz (I usually get a healthy WWV signal) and tracing the signal back through the receiver (coil pack, RF unit, IF unit, AF-AVR unit.

This is a hobby for me, so although the results are not too great right now I do enjoy the process. Thanks for the help with my troubleshooting - nice to know you are still giving your time to helping us NEWBIES :)

Steve,

At times, "YAHOO" seems to take forever..if not several days to "post" questions..etc. I myself..have posted a question to this board...and either NOT having it show up...or it showing up 1 to 3 days later. Most everyone here..works a "day job" in various parts of the United States or the "world." I myself did..until recently. I understand the "need" for immediate satisfaction/answer(s) to question(s)...but at times you must hold your breath. Sometimes..it takes time to analyze what you are asking...look at a specific schematic or rig...and give you a possible answer.
If, I may off a suggestion...BEFORE you work on a rig...especially if removing, modifying,...or anything else...take pictures, write notes, make diagrams...or whatever...so it is clear to you and, possibly others how it goes back together.

I can take a look at my 820S...but it may be a day or two, and report about my band switch alignment. I will agree that the 820(S) band switch is a pain in the a@*$ compared to the other hybrids. That's the BEST I can do.

OK..possible stupid question time...

  WHY would you want to use 5 watt, wire-wound resistors, to replace the cathode resistors in the 520? Why not use the "factory" value of(I think are) 10ohm & 1 watt 5%? carbon-comp. I have replaced several..but never used "wire-wound," capacitor "triple by-passed"
resistors...just modern metal film..or equivalent and, never had a problem......just curious

Re final cathode resistors. Yes they are a known source of trouble.
Since they were combined in parallel and a bit stressed, it
is very common for one to go high and put both of them out. I have
replaced mine with a Wirewound 5 watt resistor. However I triple by
passed it with 3 different capacitor values and it works fine (and it
won't happen again).

Gordon,

You have been wonderful in your abilities to help out those of us that have major problems with Kenwood gear, those of us with minor problems, and yes, the legions who manage to get the SG switch turned to "OFF".

Thank you for your efforts, and I wish you the best as you step back fro the keyboard and screen. I hope you can take things a bit easier, and stay in touch as you are able.

Clifford..

You should give some SERIOUS thought to un-doing your "upgrade" to your cathode resistors. The originals fail, butthey ALSO act like a fuse to prevent more serious damage in the finals section of the KW hybrids. Using wirewound resistors will increase the survivability of the resistors, but may cause other components to overheat or burn out completely in some circumstances. (We used to have similar problems with an old Motorola MPY series base station transmitter from the late 1960s. Frequent failures of the cathode resistors. We tried the
wirewound trick, and discovered why the cheap resistors kept failing. The fix was NOT cheap.)

Gordon I love the group! I know I dont participate much but I read
and having that group as a backup tosome of my vintage gear has
been a real resource! Im still my running my TS830s in fact spent more
than I should have a year ago getting one realigned and checked out.

Please know you have done an *outstanding* job! Whatever you decide
please hang around.

Very sincerely and 73.

Joe,

Didn't know about the delay. My post was Wednesday, so maybe hoping for some feedback by Friday was too much to ask. Following some other posts, though, it seems as many of the threads include multiple posts on the same day - suggesting the delay is not too long. Probably varies with internet provider, etc.

Thanks for the offer to check your rig but no need now. Thanks to the moral support and some checks to make from Terry, and some investigation and troubleshooting on my own, I am happy to report the rig is now receiving and transmitting :)

Your solution is a good one - take lots of pictures and make drawings before taking something apart. I know better than not to, but somehow just expected I could pull-it-off this time - probably cost me an extra week of down time.

Anyway, just a reminder for those "elmers" that continue to provide guidance and support. Thanks Terry and Joe. Sometimes just knowing you are there gives us the confidence we need - I call it moral support.

Thanks!!!!!!!!

Steve

Steve:

Is there a bandswitch position where the coil pack board shaft flats are side to side and the PA cage S22 switch shaft flats are at 1200 and 1500 as I described? If not, that has to be corrected.

If you can find a band position where they are properly aligned then most likely you have mis-aligned the two chain drive sprockets. If you can position those two shafts correctly at any particular band, then I would set it there and loosen the chain drive sprocket and switch the band switch to 29mhz and make sure the two shafts dont rotate and then secure the sprocket set screws and see if your problem is resolved.

Terry K9TW

Terry,

Thanks for the quick response, and thanks for going to the trouble of checking your 820 for me. When the front panel band select switch on my unit selects 29mHz the flats are not facing left and right like yours, and that part of the mechanical assemblies has not been changed. I tried aligning the other shafts per your results without success.

Unless others chime in with some alignment advice I plan to try tuning to 15MHz (I usually get a healthy WWV signal) and tracing the signal back through the receiver (coil pack, RF unit, IF unit, AF-AVR unit.

This is a hobby for me, so although the results are not too great right now I do enjoy the process. Thanks for the help with my troubleshooting - nice to know you are still giving your time to helping us NEWBIES :)

These are tough choices to make.
It takes courage to try for what is best for the Group.

My station is a 1977 HW8, a single Long-Wire,
and 1946 Bug from my first station.
Reflects my time in life.
I must temper my participation,
and let the younger guys do their part.

I own a Kenwood TS-830-S, but seldom use it.
Just read your postings, to keep up with things, to stay in touch.

Thanks for the leadership all these years.

Good luck to you and your health problems. I know the feeling well. It has been really hard to tell this 68 year old body with a 25 year old mind that I can do that stuff any more. At one time any challenge got answered, now it is a challenge to even think about answering the challenge. I just restored my TS-530S and what should have taken a week took me a whole month. Terry was a great help on this group. It overwhelms me that he can remember all this stuff and explain it so anyone can understand it. There a great bunch of other people on here as well. I am glad I found this group.
Take care of yourself and drop in and let us know how you are doing.
Our prayers are uplifted to and for you.

Well once again I will waste key strokes.

You never want to open the cathode of your final tubes during an arc over event.

Have you looked at the design of any modern day high power linear amplifiers? Where do they place tube arc over protection? They dont fuse the cathode circuit. They limit the current in the HV anode lead. Typically using a 25 to 50 ohm long path current limiting resistor or an impulse rated glitch resistor. Read Eimac Bulletin 17 or any of Ian Whites G3SEK excellent work on protecting Tetrode tubes.

That is the fix you needed in your 1960s vintage transmitter.

When 6146 arcs over and meter shunts blow open you now have an open cathode and the voltage on it will immediately rise to well over 100vdc (I have measured 125vdc) . After you recover from the pop and try to load again and key the rig and place meter in IP position you will be applying over 100vdc to your panel meter which is designed to measure a maximum of 1.75vdc. You are lucky if the initial event didnt take out your meter and if your eye was quick enough or ear sensitive enough you would have noticed the hit against the peg that occured. Why do it again intentionally?

Why would you subject your meter to this? Would you put your VOM on 2vdc range and try to measure 125vdc? Hybrid meters are scarce.

I have installed a glitch resistor in my 900vdc HV lead using a modern Ohmite Type OY unit that is designed to limit current without shattering. You dont want the glitch resistor to be sacrificial as you dont want to remove anode voltage with screen grid voltage still applied.

I have also placed 3 silicon power rectifiers in series across the 5 ohm meter shunts. I never want my 5 ohm meter shunts to open during a fault. The diode string ensures that the maximum IR drop that my meter will be exposed to is approx 2vdc. It will better survive that than 125vdc.

Kenwood realized the error of their ways when they introduced the TS530 and TS830 rigs. They added a 4.7k ohm or a 5.6k ohm resistor in parallel with the 5 ohm meter shunts. This resistor ensures that in the event that the meter shunts would open the cathode would no longer be allowed to go open circuited and there would no longer be any cathode potential rise toward SG voltage that could damage the panel meter.

The fix is to prevent the cathode from open circuiting and to install some meter protection. Fault current limiting in the HV lead close to the HV filter caps is where you want it for tube arc over events.

Clifford..

You should give some SERIOUS thought to un-doing your "upgrade" to your cathode resistors. The originals fail, butthey ALSO act like a fuse to prevent more serious damage in the finals section of the KW hybrids. Using wirewound resistors will increase the survivability of the resistors, but may cause other components to overheat or burn out completely in some circumstances. (We used to have similar problems with an old Motorola MPY series base station transmitter from the late 1960s. Frequent failures of the cathode resistors. We tried the
wirewound trick, and discovered why the cheap resistors kept failing. The fix was NOT cheap.)

If I told someone to place a fuse in the 6146 HV anode lead I am sorry. That is very bad advice. I have not done that in my or anyone elses KW Hybrid radio.

You never want to apply SG before Plate voltage and never want to interrupt Plate voltage when Screen Grid voltage is applied. The only exception to this is if the tube has cut-off bias applied.

If you have a fixed screen grid voltage supply like we have in our KW hybrids and you interrupt the Plate voltage heavy screen grid current will flow and the screen grid dissipation will be quickly exceeded and the 6146 final will almost always be damaged.

I do not remember recommending fusing the anode lead. However, if I recommended fusing the HV anode lead that was a mistake. I did not mean to say that. I meant to say to use a non-sacrificial glitch resistor close to the HV filter caps. This is one of the mods I have made to my personal rigs. I used approx 10 ohms which is on the low end of the value you want to use.

Lastly do not remove the anode caps and run your rig or remove just one anode cap and test run the rig. Should be OK in Rx mode with -100vdc cutoff bias applied, but may damage the tubes if you key the rig.

Terry K9TW .

I had the same problem. Do not remember how exactly I solved it but I think I did this:
The back switch has the detente. Set it to one end or the other.
Check the front switches for continuity to the appropriate coils on the RF board. Line them up.
I do not think you can hurt the receiver if you misalign the coil switches, It just won't work well.
The back switch should be connected to all of the coil on the lowest freq setting. I think you can eyeball that part.

Wally,

Thanks for the input. I have resolved the problem, as you have probably read by now. The delays in the posts here (Yahoo?) are hard to understand.

In case you or others have this problem I will post my solution method:

Problem: The bandswitch shaft segment in the finals cage has stops at each end of travel, so finding the first position is easy. The bandswitch shaft segment that connects the wafers on the coil pack board rotates 360 degrees without stops. To find the position for each band I used and oscilliscope and a signal generator (my antenna analyzer). The coil pack board is all passive components, so I did not need power on the unit for this test. I connected the signal generator to the antenna connector on the 820S, and monitored the RG output pin on the coil pack board. I chose a starting spot on the shaft and began trying to discover what frequency each setting was tuned to. For example, at the first position on the shaft I swept the frequency generator from low to high (1 to 30 MHz) while monitoring the output on the scope - where the output was max was the resonant frequency of the RC networks. I then rotated the shaft CW to the next position and took another reading. Once I identified the following sequence I knew where the starting position was: 13.8 MHz, 1.6 MHz and 3.09 MHz. I took more reading but that was the info I needed.

Also, I made a drawing, took notes, marked the shaft, and took lots of pictures :) Amazing how smart I got after hitting my head against the wall for a week !!!!

Thanks again for the support. Maybe this proceedure, along with your good advice, will help someone else down the road.

Steve,

At times, "YAHOO" seems to take forever..if not several days to "post" questions..etc. I myself..have posted a question to this board...and either NOT having it show up...or it showing up 1 to 3 days later. Most everyone here..works a "day job" in various parts of the United States or the "world." I myself did..until recently. I understand the "need" for immediate satisfaction/answer(s) to question(s)...but at times you must hold your breath. Sometimes..it takes time to analyze what you are asking...look at a specific schematic or rig...and give you a possible answer.
If, I may off a suggestion...BEFORE you work on a rig...especially if removing, modifying,...or anything else...take pictures, write notes, make diagrams...or whatever...so it is clear to you and, possibly others how it goes back together.

I can take a look at my 820S...but it may be a day or two, and report about my band switch alignment. I will agree that the 820(S) band switch is a pain in the a@*$ compared to the other hybrids. That's the BEST I can do.

Subject: [TS-520_820_530_830] Re: Ts-820S Band Switch Shaft Alignment

Group,

Me again. The original post here got no responses and I am baffled as t why. I am a new ham, and had a tremendous amount of support for an earlier question about how output power was calculated. Terry and Will were especially supportive.

Not sure how the wording of the problem was interpreted - maybe it just sounds to demanding or something (maybe a few days is too short a time to look for a response). Anyway, I have many years of technician experience and was simply trying to be specific.

Please let me know if this is a problem you have seen. Can I be sure the schematic shows the position of the wafer switches as aligned when the JJY selection is made on the front panel bandswitch? The affected wafer switches are on the coil pack unit and the final unit.

Joe,

Didn't know about the delay. My post was Wednesday, so maybe hoping for some feedback by Friday was too much to ask. Following some other posts, though, it seems as many of the threads include multiple posts on the same day - suggesting the delay is not too long. Probably varies with internet provider, etc.

Thanks for the offer to check your rig but no need now. Thanks to the moral support and some checks to make from Terry, and some investigation and troubleshooting on my own, I am happy to report the rig is now receiving and transmitting :)

Your solution is a good one - take lots of pictures and make drawings before taking something apart. I know better than not to, but somehow just expected I could pull-it-off this time - probably cost me an extra week of down time.

Anyway, just a reminder for those "elmers" that continue to provide guidance and support. Thanks Terry and Joe. Sometimes just knowing you are there gives us the confidence we need - I call it moral support.

Thanks!!!!!!!!

Steve

Guys and Girls, I have been Co-Owner of this group for many years. It was handed to myself and Walt from Coors Bill. He knew our Love for the hybrids and felt we would make great owners. I think we have done an outstanding job. This group is pretty easy, as it has always gotten along well except for a few sour apples. LOL. I will be deciding over the next few days who to turn my half the ownership to. My declining health prevents me from being as active as I once was. I want to Thank each and every one of you for contributing and /or being members of this great group.
Best 73,
Gordon

I am missing your point? Why are you referencing this thread? We are discussing cathode meter shunts.

Totally different resistors and nothing to do with our hybrids and the cathode meter shunts acting as fuses.

Not to mention these poor chaps on this thread are clueless as to what they are for. Very sad that you would reference this thread to support the cathode fuse position if that is your intention?

Yes a "grid stopper" can limit SG current but not so much for SG protection but for limiting distortion when the tube is driven into positive grid current in audio amplifier service.

We do have 100 ohm grid stoppers in our hybrids in series with the 6146 screen grids and they have absolutely nothing to do with fusing or protecting the 6146 tube screen grids or the screen supply.

I am not going into a long winded discussion on the purpose of grid stopper resistors. You can Google on that and read why we have these 100 ohm resistors which probably appeared in the 50s transmitter designs and have been copied ever since. I will give you a hint .....parasitic oscillations.

Another hint is never put a fuse or a blocking diode in series with your screen grid. Good protection will protect both the supply and the tube. Modern protection would use a VDR at minimum.

Again I am confused why you would want anyone to read a thread about grid stopper resistors with responses from people who are clueless?

Clifford..

You should give some SERIOUS thought to un-doing your "upgrade" to your cathode resistors. The originals fail, butthey ALSO act like a fuse to prevent more serious damage in the finals section of the KW hybrids. Using wirewound resistors will increase the survivability of the resistors, but may cause other components to overheat or burn out completely in some circumstances. (We used to have similar problems with an old Motorola MPY series base station transmitter from the late 1960s. Frequent failures of the cathode resistors. We

tried the

wirewound trick, and discovered why the cheap resistors kept failing. The fix was NOT cheap.)

Re final cathode resistors. Yes they are a known source of trouble.
Since they were combined in parallel and a bit stressed, it
is very common for one to go high and put both of them out. I have
replaced mine with a Wirewound 5 watt resistor. However I triple by
passed it with 3 different capacitor values and it works fine (and it
won't happen again).

44803. Is a lot of White Noise normal with the CW RX Filter installed?

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-22 19:20:09 UTC
From: Chris Maness
Topic: 44803 Message: 44803

In SSB and CW for the lower bands the background HF noise covers over a background white noise on my radio. However, on the higher bands where the band is quieter, I here white noise that is much broader than the 500Hz CW filter skirt. It is not from the AF stage because it decreases with the AF volume. Is this normal for this radio? Can anyone else verify this with a CW filter in the high bands?

There is a mod bulletin/article floating around the net that suggests a hash noise may be due to a bad transistor. However, if everyone else hears the same noise, I am not going to worry about it. Moreover if there is a mod for this problem, I would definitely be interested in the details. The noise is tolerable, but I would much prefer it be lower.

Here is the article in question:

http://www.radiomods.co.nz/kenwood/kenwoodts520.html

Thanks for the help guys. From this group I have received enough help to resurrect a nearly basket case TS-520S. I had fixed other problems back in 2009. Now I have a nearly perfectly working radio.

Thanks,
Chris Maness KQ6UP

Thanks Mark:

In my experience it is pretty common to find the 455Khz LO mis-adjusted due to the wrong direction in the service manual. Need to get the audio in the passband of those ceramic filters.

If Lars can get access to a audio gen would be good to do the complete alignment so he can have accurate compression indications at given mic gain setting.

Take Care

It uses a Balanced Mod to to convert your mic audio into a 455khz DSBSC signal and processes it and then a Product Detector to convert it back to audio for input to your SSB Balanced Modulator.

One of the biggest problems is people tweak on it without test gear and number one thing I find is they have tried to follow the procedure in the Service Manual and it is flawed. As I said this thing works by taking audio and applying it to its own Balanced Modulator that uses 455 khz as the LO. The manual has you set the LO for 451khz. This is outside the 455khz ceramic IF filters frequency response curve. Have to get the signal into the pass band of the ceramic filter chain that follows. It is possible to have a bad filter, but I have never seen one.

If you have a Frequency Counter you could just try setting TC-4 on IF board for 455kz at TP-3 and see what effect that has. You really cant hurt anything by making this simple adjustment. I suppose with no counter you could listen to yourself on the Moni with headphones and make small step changes on TC-4 to see if any improvement.

To really align it you need in addition to a freq counter a good stable AF generator and a means of accurately measuring low level AF signals. AC millivolt meter is easiest, but O-scope also will work.

Perfect meter for Hybrid work.

It has over 100meg input Z so can get on any tube grid and it is especially useful for AGC and ALC bus work. A Heath IM-18 or similar will pull AGC down on a TS-830 from approx 3.6vdc to around 3.0vdc and drive the S-meter up scale (you are reducing the gain of the RF and IF amps with your VTVM) and the HP-410C measures right at 3.6vdc. Bus doesnt know the 410C is connected. I use it to measure AGC threshold on all the hybrids that cross my bench before and after alignment.

Only problem with the 410B and 410C is they can be drifty and have problems with zero setting due to problems with the photo chopper and bad cal trim pots. Some of the 410C models have FET based solid state boards and no chopper, but I dont think same input Z. I do not think they put the solid state boards in the 410B model?

You can find the AC probe that goes with them but go pretty high on Ebay. They wont read very low levels of RF voltage but will read high levels. I have a couple of the original AC probes (use a special diode tube in them that gets it filament voltage thru the probe triax cable), but I only use them along with the HP453A 100:1 divider probe to measure things like the RF voltage on the plate of the 6146 finals or across the Tank circuit (around 525rms rf volts at 100 watts).

I use Boonton 92E or O-scope for most RF measurements.

The compressor is one of the better ones if aligned properly. It is kind of unusual circuit. It is not a clipper in the IF chain like the TS830. It uses a Balanced Mod to to convert your mic audio into a 455khz DSBSC signal and processes it and then a Product Detector to convert it back to audio for input to your SSB Balanced Modulator.

One of the biggest problems is people tweak on it without test gear and number one thing I find is they have tried to follow the procedure in the Service Manual and it is flawed. As I said this thing works by taking audio and applying it to its own Balanced Modulator that uses 455 khz as the LO. The manual has you set the LO for 451khz. This is outside the 455khz ceramic IF filters frequency response curve. Have to get the signal into the pass band of the ceramic filter chain that follows. It is possible to have a bad filter, but I have never seen one.

If you have a Frequency Counter you could just try setting TC-4 on IF board for 455kz at TP-3 and see what effect that has. You really cant hurt anything by making this simple adjustment. I suppose with no counter you could listen to yourself on the Moni with headphones and make small step changes on TC-4 to see if any improvement.

To really align it you need in addition to a freq counter a good stable AF generator and a means of accurately measuring low level AF signals. AC millivolt meter is easiest, but O-scope also will work.

Chris;

If you are referring to the so called "Service Bulletin" Number 21 I would not give you 10 cents for about 95% of what it contains. Be very careful to analyze any of what it directs you to do before performing it. If not sure come here and ask.

Q3 on the TS520 is the Transmit Mixer. If it is causing noise in receive mode then it must not be biased off and easy to tell as Q3 is in a socket so just pull it to see if noise goes away.

The RF board on the TS520S is different than the TS520 and the TX Mixer for the 520S is Q1.

I actually used a 4.7 Ohm 5 watt wirewound to replace the 2 10 Ohm Carbons as I have had bad experiences with carbon resistors in similar places before. BTW metal film resistors are slightly inductive too as they frequently have an etched spiral track in the film to set the resistance value. Also I like the inherent reliability of under run wire wound resistors. As long as it is HIGHLY bypassed at all likely frequencies there should be no problem at all.
Hence the triple bypass capacitors of different values so there is NO possibility of self resonance.

Some people call broad band noise as "hash" noise. I am not really sure what hash noise is or if I ever heard it. I suppose it would blanket the spectrum?

If it is an external RFI source might look at computer and peripherals especially if any of them have a switcher supply in them.

Maybe generated by one of the new CFl lamps if you are using them.

When you remove antenna or put rig on dummy load does the S-meter drop to zero and if you run RF to max and turn of the AF gain do you hear a nice smooth hiss? That would be normal noise produced internally by the receiver.

44812. Kenwood Hybrid Net Update (Sept. 22, 2013)

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-22 22:22:34 UTC
From: Mark Gilger
Topic: 44812 Message: 44812

The Saturday□s net on 40 meter had 16 stations
checking in under Good band conditions. There
were 1 new check-ins, KD4RE. Out of those, there was:

```
4 running TS-520(x)
1running TS-530(x)
5 running TS-820(x)
3 unning TS-830S
0 running TS-900

I was running my TS-940. The rest were running
non hybrids of one model or another.
```

The Sunday□s 20 meter net had 4 stations checking
in under poor band conditions. Out of those, there was:

```
0 running TS-520(x)
0 running TS-530(x)
0 running TS-820(x)
0 running TS-830S

I was running my TS-940. Seems everyone today was
running a solid state radio of one type or another.
```

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

```
If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
```

<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins

November 2012, Saturday☐s, net total = 47, Sundays total = 20

December 2012, Saturday☐s, net total = 74, Sunday☐s total = 70

January 2013, Saturday☐s, net total = 93, Sunday☐s total = 87

February 2013, Saturday☐s net total = 103, Sundays total = 87

March 2013, Saturday☐s, net total = 112, Sunday☐s total =39

April 2013, Saturday☐s net total = 52, Sunday☐s total = 29

May 2013, Saturday☐s net total = 45, Sunday☐s total = 50

June 2013, Saturday☐s net total = 30, Sunday☐s total = 27

July 2013, Saturday☐s net total = 63, Sunday☐s total = 41

August 2013, Saturday☐s net total = 82, Sunday☐s total = 50

September 2013, Saturday☐s net total = 11, Sunday☐s total = 20 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

Yes, this is the hiss I am referring to. However, it is a bit more than I am used to on a typical radio even for its vintage. It is MUCH broader than the CW filter. There are two layers of this white noise (this is not the HF background noise on the band). The louder one is effected by the RF Gain/AGC and the audio gain. There is a much fainter one that seems to be due to the audio stage by itself. It is still present even if the RF GAIN is set to minimum (AGC Voltage Max). That tells me its origin is after the CW filter, but before the audio filter. If this is normal, I am not going to worry about it. However, reiterating -- it is much louder than many other radios I have used. However, when the wide filter is in line, it blends in with the HF background noise to the point I have not noticed it before. It is entirely possible that this is normal for the design. It just seems like the greatest noise would be generated at the stage of greatest gain. I would imagine this would be before that CW filter, and therefore the Nyquest/Shot noise would be shaped by the filter also. Just my book thoughts and observations speaking -- not from experience.

The shape of the noise frequency response in relationship to the HF background noise makes it REALLY stand out on the high bands. An external

audio band pass filter would cure this if I found it too annoying, but if there is something wrong inside I would like to fix it.

Tnx es

44814. RE: [TS-520_820_530_830] RE: TS-820 service and alignment instrument...

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-22 22:51:53 UTC
From: Rick
Topic: 44804 Message: 44814

Thanks, Terry for the info. Thankfully, I already have the AC probe and even have an extra tube for it. I also have an old Heathkit VTVM and an RCA RF probe adaptor that slips on the end of the Heathkit probe to do the more sensitive measurements.

I think I'm about ready to dive back into the TS-820 I was working on before medical issues (triple bypass) sidelined me for a while. I would have sworn I had a sweep generator from my TV repair days, but I can't seem to find it now. The years have a way of hiding things or making them disappear all together.

Do you or anyone on the reflector have any suggestions for a reliable, yet not too expensive, sweep generator capable of the slow sweep required?

My old scope is limping along like me, but I think it'll do the trick.

Thanks again for the information. I'm sure I'll be asking more questions as this project gets under way.

Rick/K5IAR

Subject: [TS-520_820_530_830] RE: TS-820 service and alignment instrument...

Perfect meter for Hybrid work.

It has over 100meg input Z so can get on any tube grid and it is especially useful for AGC and ALC bus work. A Heath IM-18 or similar will pull AGC down on a TS-830 from approx 3.6vdc to around 3.0vdc and drive the S-meter up scale (you are reducing the gain of the RF and IF amps with your VTVM) and the HP-410C measures right at 3.6vdc. Bus doesnt know the 410C is connected. I use it to measure AGC threshold on all the hybrids that cross my bench before and after alignment.

Only problem with the 410B and 410C is they can be drifty and have problems with zero setting due to problems with the photo chopper and bad cal trim pots. Some of the 410C models have FET based solid state boards and no chopper, but I dont think same input Z. I do not think they put the solid state boards in the 410B model?

You can find the AC probe that goes with them but go pretty high on Ebay. They wont read very low levels of RF voltage but will read high levels. I have a couple of the original AC probes (use a special diode tube in them that gets it filament voltage thru the probe triax cable), but I only use them along with the HP453A 100:1 divider probe to measure things like the RF voltage on the plate of the 6146 finals or across the Tank circuit (around 525rms rf volts at 100 watts).

I use Boonton 92E or O-scope for most RF measurements.

44817. TS-830S external VFO with DDS

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-23 00:36:22 UTC
From: <va7deo@...>
Topic: 44817 Message: 44817

I'm looking for the pinout descriptions for the external VFO plug so I can use a DDS as an external VFO. The TS-830S manual I have doesn't have the pinouts for all the rear connections.

44818. RE: Re: [TS-520_820_530_830] RE: Compressor adjustment...

Jan:

Ray is strong here near South Bend Ind, but must say that Mark normally beats the "school bus". Maybe Marks 40 meter rhombic?

I will be interested to hear you and Jimmy.

HA! Thanks Terry for the kind words, but yeah, when the 4CX1500B is finally built, I hope I might be as strong as WB0IQK (Mark).

Jan N8CBX

wagstw46@... wrote:

No you are just thinking of another good guy and that is Jan N8CBX who runs the TS-820S and is building high power grid driven tetrode amp and when he gets it on air you will have to disconnect your antenna!

Terry

Excuse me, it was Lars that you helped, not Jan. Old age creeping into the picture here.
Mark

At 03:17 PM 9/22/2013, Mark Gilger wrote:

Terry,
You helped Jan out on his 820 compressor alignment a while back and would like to report that he checked into the Saturday net and turned it on. It sounded great. So your procedure works a-ok. In his case he listened on another receiver and just tweaked it in until it sounded good.

Thanks,
Mark, WB0IQK

At 09:24 AM 9/18/2013, wagstw46@... wrote:

Lars:

The compressor is one of the better ones if aligned properly. It is kind of unusual circuit. It is not a clipper in the IF chain like the TS830. It uses a Balanced Mod to to convert your mic audio into a 455khz DSBSC signal and processes it and then a Product Detector to convert it back to audio for input to your SSB Balanced Modulator.

One of the biggest problems is people tweak on it without test gear and number one thing I find is they have tried to follow the procedure in the Service Manual and it is flawed. As I said this thing works by taking audio and applying it to its own Balanced Modulator that uses 455 khz as the LO. The manual has you set the LO for 451khz. This is outside the 455khz ceramic IF filters frequency response curve. Have to get the signal into the pass band of the ceramic filter chain that follows. It is possible to have a bad filter, but I have never seen one.

If you have a Frequency Counter you could just try setting TC-4 on IF board for 455kz at TP-3 and see what effect that has. You really cant hurt anything by making this simple adjustment. I suppose with no counter you could listen to yourself on the Moni with headphones and make small step changes on TC-4 to see if any improvement.

To really align it you need in addition to a freq counter a good stable AF generator and a means of accurately measuring low level AF signals. AC millivolt meter is easiest, but O-scope also will work.

Yes Mark when I am working on the bench I monitor. Not often any tech questions you cant handle. Not much I can add other than to the numbers.

Terry

Excuse me, it was Lars that you helped, not Jan. Old age creeping into the picture here.
Mark

At 03:17 PM 9/22/2013, Mark Gilger wrote:

Terry,
You helped Jan out on his 820 compressor alignment a while back and would like to report that he checked into the Saturday net and turned it on. It sounded great. So your procedure works a-ok. In his case he listened on another receiver and just tweaked it in until it sounded good.

Thanks,
Mark, WB0IQK

At 09:24 AM 9/18/2013, wagstw46@... wrote:

Lars:

The compressor is one of the better ones if aligned properly. It is kind of unusual circuit. It is not a clipper in the IF chain like the TS830. It uses a Balanced Mod to to convert your mic audio into a 455khz DSBSC signal and processes it and then a Product Detector to convert it back to audio for input to your SSB Balanced Modulator.

One of the biggest problems is people tweak on it without test gear and number one thing I find is they have tried to follow the procedure in the Service Manual and it is flawed. As I said this thing works by taking audio and applying it to its own Balanced Modulator that uses 455 khz as the LO. The manual has you set the LO for 451khz. This is outside the 455khz ceramic IF filters frequency response curve. Have to get the signal into the pass

band of the ceramic filter chain that follows. It is possible to have a bad filter, but I have never seen one.

If you have a Frequency Counter you could just try setting TC-4 on IF board for 455kz at TP-3 and see what effect that has. You really cant hurt anything by making this simple adjustment. I suppose with no counter you could listen to yourself on the Moni with headphones and make small step changes on TC-4 to see if any improvement.

To really align it you need in addition to a freq counter a good stable AF generator and a means of accurately measuring low level AF signals. AC millivolt meter is easiest, but O-scope also will work.

Been a very long time since I have thought or read about Thermal or Shot noise. I think some guy Kelvin is involved too!

Maybe a You tube video for the other TS520S owners with CW filters installed would help?

On Sun, Sep 22, 2013 at 2:50 PM, <wagstw46@...> wrote:

Some people call broad band noise as "hash" noise. I am not really sure what hash noise is or if I ever heard it. I suppose it would blanket the spectrum?

If it is an external RFI source might look at computer and peripherals especially if any of them have a switcher supply in them.

Definitely internal source because the noise is independent of antenna/dummy load configurations.

Maybe generated by one of the new CFl lamps if you are using them.

See above.

When you remove antenna or put rig on dummy load does the S-meter drop to zero and if you run RF to max and turn of the AF gain do you hear a nice smooth hiss? That would be normal noise produced internally by the receiver.

Yes, this is the hiss I am referring to. However, it is a bit more than I am used to on a typical radio even for its vintage. It is MUCH broader than the CW filter. There are two layers of this white noise (this is not the HF background noise on the band). The louder one is effected by the RF Gain/AGC and the audio gain. There is a much fainter one that seems to be due to the audio stage by itself. It is still present even if the RF GAIN is set to minimum (AGC Voltage Max). That tells me its origin is after the CW filter, but before the audio filter. If this is normal, I am not going to worry about it. However, reiterating -- it is much louder than many other radios I have used. However, when the wide filter is in line, it blends in with the HF background noise to the point I have not noticed it before. It is entirely possible that this is normal for the design. It just seems like the greatest noise would be generated at the stage of greatest gain. I would imagine this would be before that CW filter, and therefore the Nyquest/Shot noise would be shaped by the filter also. Just my book thoughts and observations speaking -- not from experience.

The shape of the noise frequency response in relationship to the HF background noise makes it REALLY stand out on the high bands. An external audio band pass filter would cure this

if I found it too annoying, but if there is something wrong inside I would like to fix it.

Tnx es

In SSB and CW for the lower bands the background HF noise covers over a background white noise on my radio. However, on the higher bands where the band is quieter,! I here white noise that is much broader than the 500Hz CW filter skirt. It is not from the AF stage because it decreases with the AF volume. Is this normal for this radio? Can anyone else verify this with a CW filter in the high bands?

There is a mod bulletin/article floating around the net that suggests a hash noise may be due to a bad transistor. However, if everyone else hears the same noise, I am not going to worry about it. Moreover if there is a mod for this problem, I would definitely be interested in the details. The noise is tolerable, but I would much prefer it be lower.

Here is the article in question:

http://www.radiomods.co.nz/kenwood/kenwoodts520.html

Thanks for the help guys. From this group I have received enough help to resurrect a nearly basket case TS-520S. I had fixed other problems back in 2009. Now I have a nearly perfectly working radio.

Thanks,
Chris Maness KQ6UP

44822. 520s send/rec switch not working

Hi Group, sorry if this has been posted already, but i am having problems find things here with the new group look.

After many, many years my send/rec switch stopped operating.(TS-520S) It fires the relay occasionally. It started when i tried to tune on 80 meters for the first time in a long time. Click, and nothing. Switched back down to 20 and it worked intermediately. So from past experience, would this be the switch, the relay, or power to the relay? .....Possibly the band switch??

I havent begun to even look at it yet tonight..too late to start. I will try keying the relay via the mic tomorrow, and a few other things. I wanted to get a post going so i'll have some input to think on while I look at the schematics.

Thanks

Steve

Steve,

  Anything's possible but, I doubt the "send/rcv" switch is bad. I would more than likely suspect RL-2.
It's on the bottom of the rig, next to the final amplifier board, under the metal shield.
DO NOT ATTEMPT
TO REMOVE THIS WITHOUT FIRST MAKING SURE THAT ALL THE HIGH VOLTAGE IS GONE!
This relay has contacts that can be cleaned by various methods. Contact cleaner and some card stock works good.
Try this first. Then clean your band switch wafer contacts. Kinda gave yourself a clue...80-meters has not been used in
a long time...could equal gunk on the contacts.....went to 20meters and it worked fine.

Steve,

  I would suspect RL-2 first, it's under the metal shield by the final amp board. UNPLUG RIG!, let it sit, then check
to see if there's anymore high voltage lurking around. Remove shield...remove relay (it pulls out), you will need a fine
screwdriver or similar tool to remove the plastic cover from the relay. Use some card stock wetted with contact cleaner
and clean all the contacts...some canned air comes in handy here. Re-install relay and check for operation.
There's kinda of a clue here too: 80 meters has not been used in "a long time." The bandswitch wafer contacts
may have gotten some corrosion on them from no use, but worked correctly on 20 meters. Clean all the bandswitch wafer
contacts with contact cleaner/lube and blow off with canned air. I'll wager that all should be fine now

I was interested to see the suggestion that the 10 Ohm cathode resistors were a sort of safety fuse!!
The actual final current is measured across them as a shunt and if they fail this can do terrible things to the TS820's meter. In fact mine is a replacement because of this very problem and it took a lot of searching to find a suitable meter, even then it required another external shunt as it was more sensitive than the original.
So, A fuse that can't be replaced unless you dismantle the unit and expose the 800 volt power!!!! That just ain't good design in my book.
Safe, reliable and stable resistors in that place are much more important.
As to final amp strains. Well that is definitely true, it is easy to damage even 6146B's in the TS 820.
But isn't that what the meter is for. Also the original fan is very inadequate, mine has been replaced with a 12 volt computer fan and the case modified to improve airflow.
But then some of these problems are also due to Kenwood's poor final tank circuit design.
It means that the final can be slightly less than 50% efficient on certain bands.
All my home brew linears approach 68% on 14 MHz. Thats a Helluva lot less wasted heat.

Sorry to be an old anti appliance operator type, but if you don't know your Volts, Amps and Watts why are you involved with Ham radio at all?
These days it is no longer a question of merely wanting to communicate.

Thanks. I was looking at the service manual.

I'll guess that the VFO control pin is what switches from the internal to external VFO. I'll have a look at the schematics to see if I can verify that.

What happens when you try to key the rig with the Mic PTT?

Keying the rigs aux and TR relays is not band dependent.

If you can key rig with the Mic PTT reliably then problem is the Send/Receive switch.

If you cannot key rig with the PTT then go to VOX board and ground SS terminal and measure RL terminal. Should see 12vdc on RL each time you ground SS.

Not likely bad relay closing coil.

Hi Group, sorry if this has been posted already, but i am having problems find things here with the new group look.

After many, many years my send/rec switch stopped operating.(TS-520S) It fires the relay occasionally. It started when i tried to tune on 80 meters for the first time in a long time. Click, and nothing. Switched back down to 20 and it worked intermediately. So from past experience, would this be the switch, the relay, or power to the relay? .....Possibly the band switch??

I havent begun to even look at it yet tonight..too late to start. I will try keying the relay via the mic tomorrow, and a few other things. I wanted to get a post going so i'll have some input to think on while I look at the schematics.

Thanks

Steve

A voice of reason from the wilderness! Thank You Clifford.

Try Bob Mansker for an original 500ua meter movement. Also see them from time to time on Ebay in the $20.00 range.

As to EASY to damage the 6146 finals here is how to do it for certain:

1. Anode to suppressor grid arc over due to internal out-gassing and air inleakage around seals. NOS spares sitting on shelf for 30 plus years are susceptable. I have done hi-pot testing on variety of used pulls and NOS and get wide range of leakage current. Tubes must be able to withstand approx 1400 volts RF swing at the anode at 100 watts output. I test to minimum of 1600vdc to simulate this condition. Some spares cannot hold off that level while others will show less than 5ua leakage current. Some can hold off up to 2000 vdc or more.

2. Thermal run away. If you lose the negative operating bias on the control grids (can happen while trying to adjust the bias voltage pot to set resting plate current to 60ma). Plate current will peg very hard and plates glow cherry red and deform before you can act to unkey the rig.

3. If radio has been QRO modified and routinely loaded to 300 ma or more. This wont cause instant failure like 1 and 2 above but can shorten the tube life.

4. Mis-tuning when loading the rig is kind of a myth as to it causing tube damage or cathode meter shunt failure. Not likely to cause instant failure. Long off resonant key down time isnt good, but not likely to cause catastrophic failure. If you are experienced you can play with this and observe plate current for various combinations of Plate Load and Tune capacitor positions and note the plate current or measure the IR drop across the 5 ohm meter shunts.

As to inefficient Tank about only place that it is a problem is on 10 meters in my experience. Common problem for multi-band tanks as the designer is stuck with high level of parasitic capacitance that prevents them from using optimum LC ratios and optimum Q in both the Driver stage tank and the pi-network. You will see no capacitors used in the Driver stage tank circuits on higher bands due to parasitic capacitance that exists from the internal capacitance of the tubes and the circuit pc traces and bandswitch. That capacitance is significant and you are forced to use an inductor that will resonate with it that is not optimum LC ratio.

If you were a 160 thru 10 meter designer where would you place the compromise and where would it be easiest to correct using external means? Of course on 10 meters. Very easy to compensate for transmitter in-efficiency by employing a high gain directive antenna on 10 meters that would not be possible on 160 or even 80 meters.

So we have all pretty much come to accept that our multi-band transmitters, transceivers, and high power linear amps that it is "normal" to have lower output power on 10 meters and perhaps somewhat lower on 15 meters. Also, not easy to make a solenoid wound Plate choke that offers optimum inductance across this broad range but that is another subject.

Thanks for putting on your Fundamentals thinking hat.

44830. Cathode resistors as fuses

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-23 14:25:49 UTC
From: Mike
Topic: 44830 Message: 44830

I continue to read that some hams appear to believe the cathode resistors act as fuses to protect the final amplifier in the event of improper tuningof the final amplifier. What I have not seen from any of these hams isany supporting facts to support such a notion other than they read it on a website and/or a fellow ham told them so.

I mean on disrespect towards anyone so please don't take any of what I am going to say and show, the wrong way.I am simply showing you that the cathode resistors are not acting as fuses.

Go to Gordon's website and download the TS-830's high resolution schematic.

Use the 1.36VDC cathode voltage and the 5 ohms (four 20 ohm resistors connected in parallel) to calculate the transmit cathode current and power dissipation levels in the cathode circuit. Each cathode resistor is 20 ohms and each resistor is rated at 1/2 watt. Connecting four 1/2 watt 20 ohm resistors in parallel equals a power rating of 2 wattsand a total resistance of 5 ohms.

The cathode current with 1.36VDC cathode voltage is .272 amps (272ma)

1.36 / 5 = .272 amps

The power consumed in the cathode circuit is .36992 watts (370mw)

.272 x .272 x 5 = .36992 watts (370mw)

Each cathode resistor will have .068 amps (68ma) flowing through it

1.36 / 20 = .068 amps (68ma)

Each cathode resistor will dissipate .09248 watts (92mw)

.068 x .068 x 20 = .09248 watts (92mw)

Even if the cathode current rises to a significantly higher level of 390ma from improperly tuning the final amplifier, the cathode voltage will rise to 1.95VDC:

.390 x 5 = 1.95VDC

The cathode current with 1.95VDC cathode voltage is:

1.95 / 5 = .390 amps (390ma)

and the power dissipated in the cathode circuit will be.7605 watts (760mw)

.390 x .390 x 5 = .7605 watts (760mw)

Each cathode resistor will have .0975 amps (97.5ma) flowing through them

1.95 / 20 = .0975 amps (97.5ma)

and each cathode resistor will dissipate .190125 watts (190mw)

.0975 x .0975 x 20 = .190125 watts (190mw).

This clearly shows even with 390ma of cathode current due to improper tuning of the final amplifier, the power dissipated in each cathode resistor and the total power dissipated in the cathode circuitdoes not equal or exceed the individual cathode resistor's 1/2 watt power rating nor does it equal or exceed the total 2 watt power rating of all 4 cathode resistors connected in parallel! The calculations above simply do not support the belief that the cathode resistors act as fuses, it's that simple. The cathode resistors, even with 390ma of cathode current due to improper tuning of the final amplifier, will NOT blow/explode/crack/burn up or fail as many hams seem to think/believe they will! The calculation figures simply do not support such a beliefanda resistors does not act the same way a fuse does in a circuit.

Terry

To make tracing easier i went and had the TS 830 color schematic blown up to 2x3,a lot better on old eyes to follow.
I took all the voltages from the abbreviation schematic,to make sure i had not missed any on the connectors.
The one we did not discuss was the minus 6 volts.I had it on the counter unit,but not on the audio or IF board.I was able to trace the wire back to the -6 volt switch board and found it had broken off.
After soldering the wire back on the post i now had white noise,if that's what you call it when i turned the rig on
I now have the whole front panel removed to get at the +0.5 switch as three wire's have broken off that switch.
Needed a good cleaning anyway.

I still have very week signal's or high attenuation on all bands.The high bands have higher s-meter reading on the SSG than the lower bands,with 21 MHz being the strongest.
Question
My Rf board is good except for the mixer and ant coils.
Is there any were one can get sub's for these coils.The rubber band trick works ok,but makes it harder to adjust the coils.
Once i get it back together i can go on with the injection steps on the IF board
I tried to get a Rf probe on Ebay for my VTVM but got outbid,so will roll my own.
Which diode would you recommend for a RF probe.

I am not sure on how many owners had this Ebay special before me,but even the wire's are dull in color compared to my other rigs.
The only reason i have not flogged it off,as it makes a good training radio for me to learn on.

Again, thanks for the tip, Terry. Man, they are right proud of those sweep generators. I'll keep my eyes open for something I can afford. I realized after you mentioned it the old TV sweep generator wouldn't do the job. That's one less thing I have to look for. It seems I am always searching for something.

I'm sorry to hear about the stents and blood clots in the lungs. You were wise to take care of it while stents were still an option. I made the mistake of waiting too long and the arteries of the heart were just too blocked to use stents. It's my understanding they are extremely successful. I too am on blood thinners, Pradaxa and will be for the rest of my life. It's great you're able to ride again. I walk as best I can. I unfortunately also have a very bad back which limits my activity. Oh,,, the trials and tribulations of getting old never seem to cease. I agree with you completely, it's best to take it one day at a time.

Thanks again for your assistance.

Good that you have the 11036A probe and xtra tube. Sounds like you are good to go for RF voltage measurement. A must for diagnosing low or no RF drive.

Well a TV sweep gen isnt too good for the narrow bandwidth xtal IF filters or BPF you will want to look at in these hybrids.

Unfortunately Sweep gens are not cheap. Wavetek 2001/2002 can be had for around $200. Wavetek 1080/1081 are nice but minimum around $500.

Next step up around $1400 is a 2 port USB VNA like the Array Solutions or the Rigol DS815-TG spectrum analyzer.

There may be a DDS Sweep gen available that I am not familiar with. Maybe even a kit?

I like the Waveteks as they have front panel bnc input for Marker signals.

I have a couple of stents from 2005 heart attack and hopefully no bypass in my future. Will cross that bridge when/if need to. Recently had blood clots in both lungs so dodged a bullet and lucky to be typing this now. Just saw doc on Friday and will be on Xarelto until at least Dec. Back to riding my bike now and just taking one day at a time.

If you get the 410B try measuring the AGC bus voltage with it then use your Heath VTVM and any and all DMMs or VOMs that you have. Fun to see what happens with each meter and when the receiver shuts down and S-meter drives near full scale you will understand importance of meter input Z for hybrid work.

Terry K9TW

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Thanks, Terry for the info. Thankfully, I already have the AC probe and even have an extra tube for it. I also have an old Heathkit VTVM and an RCA RF probe adaptor that slips on the end of the Heathkit probe to do the more sensitive measurements.

I think I'm about ready to dive back into the TS-820 I was working on before medical issues (triple bypass) sidelined me for a while. I would have sworn I had a sweep generator from my TV repair days, but I can't seem to find it now. The years have a way of hiding things or making them disappear all together.

Do you or anyone on the reflector have any suggestions for a reliable, yet not too expensive, sweep generator capable of the slow sweep required?

My old scope is limping along like me, but I think it'll do the trick.

Thanks again for the information. I'm sure I'll be asking more questions as this project gets under way.

Subject: [TS-520_820_530_830] RE: TS-820 service and alignment instrument...

Perfect meter for Hybrid work.

It has over 100meg input Z so can get on any tube grid and it is especially useful for AGC and ALC bus work. A Heath IM-18 or similar will pull AGC down on a TS-830 from approx 3.6vdc to around 3.0vdc and drive the S-meter up scale (you are reducing the gain of the RF and IF amps with your VTVM) and the HP-410C measures right at 3.6vdc. Bus doesnt know the 410C is connected. I use it to measure AGC threshold on all the hybrids that cross my bench

before and after alignment.

Only problem with the 410B and 410C is they can be drifty and have problems with zero setting due to problems with the photo chopper and bad cal trim pots. Some of the 410C models have FET based solid state boards and no chopper, but I dont think same input Z. I do not think they put the solid state boards in the 410B model?

You can find the AC probe that goes with them but go pretty high on Ebay. They wont read very low levels of RF voltage but will read high levels. I have a couple of the original AC probes (use a special diode tube in them that gets it filament voltage thru the probe triax cable), but I only use them along with the HP453A 100:1 divider probe to measure things like the RF voltage on the plate of the 6146 finals or across the Tank circuit (around 525rms rf volts at 100 watts).

I use Boonton 92E or O-scope for most RF measurements.

Topic: 44833 Message: 44833

Had a nice discussion about keeping tubes alive on a old timer's round table a few days. The consensus with the old timer's was that tube rigs should be kept on 24/7 to extend their life. I am certain there is a point of diminishing returns with this statement. If one used the radio once per day, or just a couple of time per week would it not be better to shut 'er down for the in between time. There is also the issue of diminishing returns with mains power being consumed versus the cost of new tubes.

I also do not run at greater than 100Watts.

Terry had mentioned some NOS 6146B's were gassy. That is disconcerting. I did not know the were sealed against the base. I guess that is where sweep tubes have the advantage. I have yet to come across a bad NOS tube. However, I have only messed with the small 12AX7 types.

Terry, if we send you tubes can you verify that these babies won't arc over? I wouldn't even mind if you charged me a fee for this. I am thinking of getting a set and putting them away for a rainy day. I am really enjoying my 520 Sugar -- white noise on CW and all :D I have been working DX on 40m. This is something new to me.

One thing that works well is to keep the filaments powered at a reduced voltage. Even reducing the voltage 10% extends the life a lot.

Subject: [TS-520_820_530_830] Extending The Life of Tubes?

Had a nice discussion about keeping tubes alive on a old timer's round table a few days. The consensus with the old timer's was that tube rigs should be kept on 24/7 to extend their life. I am certain there is a point of diminishing returns with this statement. If one used the radio once per day, or just a couple of time per week would it not be better to shut 'er down for the in between time. There is also the issue of diminishing returns with mains power being consumed versus the cost of new tubes.

I also do not run at greater than 100Watts.

Terry had mentioned some NOS 6146B's were gassy. That is disconcerting. I did not know the were sealed against the base. I guess that is where sweep tubes have the advantage. I have yet to come across a bad NOS tube. However, I have only messed with the small 12AX7 types.

Terry, if we send you tubes can you verify that these babies won't arc over? I wouldn't even mind if you charged me a fee for this. I am thinking of getting a set and putting them away for a rainy day. I am really enjoying my 520 Sugar -- white noise on CW and all :D I have been working DX on 40m. This is something new to me.

I also have a TS-520...love the rig.

As to the issue of gassy NOS tubes, I think it's more a gamble than a solid fact. I've used many a NOS with no problems, but that's not to say that it can't happen, there is always that risk. I just try to make sure the seller of the tubes has some kind of guarantee, or a disclaimer that says otherwise.

As to the keeping the valves lit all the time to make 'em last longer, that's hard to say. But I think your argument is correct; this may be a point of diminishing returns. The benefits may not outweigh the cost in the long run.

Yes I have the big schematic as well. Have one laminated and other real dog eared one that I mark on and one brand new in the mailing tube as a spare. Very helpful.

If you have no -6 at audio board then you will have no Receive bias RB1 at RF amp on RF board. You want to turn off Q1 RF amp in transmit mode. You will also have no cutoff bias (TB) for the TIF amp on the IF board. Also will have no AGC action as -6 supplies AGC amp transistor Q10. Also, the -6 is used to back bias the agc detector diodes to set the AGC threshold. So missing it at Audio and IF boards is a big deal. I thought we had talked about it when we discussed S-meter action. Perhaps not. Lot of ground has been covered.

Yes this rig sure is a mess and will present a challenge and as you say a learning experience for you. This is one if on the bench would be no way to bill all the hours you would have in it. I dont work on them any more.

I wrote a pretty detailed primer on why need single diode and multi-diode probe and what characteristics you should look for in a diode, but dont remember what Message number it is. Not sure with this new format if you could ever find it. Things like that probably should go in the files section. Maybe you can try searching on RF probes? It is important to understand that the diode is seeing the peak and what the PIV will be in selecting a diode. We dont care too much about flat frequency response and real precise voltage measuring.

If you can find a germanium signal diode that is what I would opt for. They will give you the best sensitivity. 1n34A, 1n60, 1n270 will all work. Dont use a silicon fast switcher like a 1n914 or 1n4148. They will work but barrier voltage is too high. If you cant find a germanium then a Schottky like a 1n5711 will work. Scotts Elecronics (crystal set parts) state side sells them on his website.

Just remember that you cant get on plate of Driver tube or the control grids of the 6146 finals with a single diode probe. Approx 30 to 35 volts is max and will destroy the diode attempting to measure the RF drive levels at those two locations. I would make a 3 diode probe for the higher RF voltage levels you will want to measure. It wont be good for low levels so you use the 1 diode probe for that. This is why Heath offered the 309C and the PK-3.

Terry

To make tracing easier i went and had the TS 830 color schematic blown up to 2x3,a lot better on old eyes to follow.
I took all the voltages from the abbreviation schematic,to make sure i had not missed any on the connectors.
The one we did not discuss was the minus 6 volts.I had it on the counter unit,but not on the audio or IF board.I was able to trace the wire back to the -6 volt switch board and

found it had broken off.
After soldering the wire back on the post i now had white noise,if that's what you call it when i turned the rig on
I now have the whole front panel removed to get at the +0.5 switch as three wire's have broken off that switch.
Needed a good cleaning anyway.

I still have very week signal's or high attenuation on all bands.The high bands have higher s-meter reading on the SSG than the lower bands,with 21 MHz being the strongest.
Question
My Rf board is good except for the mixer and ant coils.
Is there any were one can get sub's for these coils.The rubber band trick works ok,but makes it harder to adjust the coils.
Once i get it back together i can go on with the injection steps on the IF board
I tried to get a Rf probe on Ebay for my VTVM but got outbid,so will roll my own.
Which diode would you recommend for a RF probe.

I am not sure on how many owners had this Ebay special before me,but even the wire's are dull in color compared to my other rigs.
The only reason i have not flogged it off,as it makes a good training radio for me to learn on.

Use a low level to inject 8.830 at RIF on IF board and couple output of sig gen thru about a .01uf cap. Nothing more than 5 mv. Also, a couple of the cans will have very little effect on signal level on the S-meter as you turn the core. Do not worry about those at this time. If you get some improvement in S-meter indication suggest you lower the sig gen level and make a 2nd pass. What you are looking for is something that has been grossly mis-tuned that will make IF chain come alive.

If doing IFT alignment does not produce significant improvement in Rx sensitivity then I think time to remove the IF board and do good visual inspection on all the molex pins under magnification and look at all the traces for damage and signs of cobbled repairs. Can have lifted pads and traces, solder bridging, wire jumpers, maybe even a blown trace etc.

I am pretty sure I had you measure Carrier Oscillator and VBT Osc previously and you reported they were to spec. I think we also measured all the DC supply voltages to the board.

We have not yet tried injecting signals in to the IF filters and measuring the output to verify filters are good.

We can do signal injection/tracing next to find where the attenuation is occurring or you can pull board and do good visual. If you have already done that then only thing left (assuming that all necessary signals and DC inputs are present on the board) is to do signal injection/tracing.

I have to trust you when you report back that you have the signals and voltages I ask you to check and that you have the test gear to detect and measure these required inputs and know how to use them. I am not there to witness any of these measurements. I can tell you however it is pretty common for me to hear back from someone I am trying to help that previously reported findings were not correct.

I mean no disrespect it is just a pretty common for this to happen.

I believe you are saying that when you inject 8.830 @500mv from your RF sig gen into the RIF terminal on the IF board you have a loud high frequency tone that you can vary with the audio gain pot (not tunable with the VFO), but the S-meter level is only at S1?

I think we measured RFG at Conn 8 with RF gain pot full CW? It should be 3.6vdc

I think we measured AGC bus voltage at Conn 15? .Need to use nothing less than a 10 meg DMM. It will pull the AGC bus down from 3.6 to close to 3.0vdc or slightly less.

Have you measured these two voltages? Normally if the AGC bus voltage is low the S-meter will be driven up scale with no signal applied unless the S-meter driver circuit is bad.

Have you ever performed the IFT alignment? You can perform the procedure in the maintenance section of the operating manual or the steps in the service manual.

Terry K9TW

Terry

Now i remember what i said about loud but no s-meter reading,it is this test i did and now i have redid it with the 8.8830 injection at conn 6

I got S1 meter reading with 500 mv injection in con 6 and same on the RF board con 5 pin 2

Don

So trusting that the audio board is working as it should and can process the output of the Product Detector, then the problem now is very weak Marker and very weak off air signals

and low or no S-meter indication. Dont worry about weak moni at this point.

So this is place I would use RF sig generator and split the problem. Is it on the IF board or the RF board (or both but not likely). If you want to work back from the Audio Board then I would inject 8.830 mhz into the RIF terminal on the IF board and see if you can hear it loud and good S meter indication. If you can then move on to the RF board. If you cannot get back and we can talk about signal injection/tracing on the IF board.

Inject 8.830mhz at Conn 6 on IF board. You dont need any modulation. -73dBM/50uv should give approx S6. -53dBm/500uv should give approx S9. -33dBm/5mv should give approx +20 over.

I am not saying that all NOS 6146 that have set around for 35 years will off gas or have air in-leakage at the pin to glass interface seal area.

I am saying it is very likely wont have a pure inert vacuum environment and this is the primary reason for tube arc overs other than foreign conductive objects inside the envelope and I think American mfg standards and QC was good and not likely any foreign objects or conductive hairs bridging the space between the elements.

What started me on this journey is I had 4 sets of 6146B supposedly NOS spares. Two GE and two RCA. I had them for years and never used them. I popped the cathode resistors one day in a QSO when I keyed the mic and started speaking. I picked the pieces of cathode resistors out of rig, replaced them and installed set of the GE NOS spares, neutralized them and put covers back on. Next day loaded rig and was going to work some CW. Keyed the rig again and bang.

Went thru same repair again and installed set of the RCA NOS spares. This time left covers off. Loaded rig and all was fine. About 3 days later bang again. This time my 500ua panel meter bit the dust.

This is when I wrote Tom Rauch W8JI and asked for some help and posted on QRZ and got all the usual responses about how the cathode "fuses" were doing there job. I even had guys trying to convince me that they were not only fuses but cathode bias resistors and degenerative feedback resistors. All of course BS. Even got those who said problem was with the KW rig as they ran Heath transceivers and never experienced a blown cathode meter shunt resistor since building the rig new in the 70s. .

Tom saw this and threw the BS flag. He runs many boatanchor rigs with 6146 finals in them and years ago bought 6146 tubes in the case lot. He also has a DC hipot and tests them before using and finds a pretty high leakage rate. He suggested that I try Sylvania 6146W JAN tubes. I use them now and have had good luck with them. He also helped me with the mod to protect the panel meter. I have added MOVs on the screen grids and a HV supply glitch resistor. I no longer have any open cathode resistors. Knock on wood.

The point is you really dont know if your spare 6146 finals that have been sitting on your shelf are NOS or not. You may be able to decipher the date code and it is likely they are 25 to 30 years old since they have not been manufactured state side in many years. That fact alone tells you that there is some risk in using. No amount of "cooking" or "gettering" is going to help. You can install them and they may work fine or they may arc over and pop your cathode resistors. Many people install new cathode resistors and try it again and things are fine and tube does not arc over again. I never do that as my panel meter is worth more than any 6146 tube and I dont want to stress it multiple times or the HV caps or the HV rectifier diodes or the power transformer.

So again no way to tell if you have a NOS spare or any spare that is a viable spare when you reach for it other than to DC hipot and see what leakage current you have in a stepped high voltage test. DC hipot is of course not a common piece of test gear in most ham shacks . So absent installing protection on your final board it is as Bob says a gamble.

Up to you how you deal with it.

Terry

Yes that was well spent money.I also got one of the PLL board and it
came out real nice.$10 EACH.
As i am lucky to have four good working hybrids,three ts830's and one
ts520s,this Ebay special has been a good training rig with your help.
If it was not for this forum,i would be up well you know S--- creek with
out the paddle.
I don't like to pawn off junk to other hams or anybody else.I would
ratter sell it as parts or throw it in the creek.
No we did not talk about the -6 volts,well i had made mention of it,but
i guess it was not were you wanted me to test.
You made no mention of a source for coils for the RF board.Do you know
the inductance for them.Maybe i could rewind them.
The coils with the bigger slugs have not been a problem like the smaller
ones,3.5,7 MHZ.
I do have a L/C from alldigital.
Thanks for pointing that out about the different probes as i did not
know that.
I just did a startpage search on the probes and found the pk3 schematic
with the three diodes.
Guess i will build the two or buy the two different ones on Ebay.
I see on Ebay there is a PK1 too.
I see they are advertising cougar women on our group site now hi hi.

Sorry I forgot about the Drive and Mixer coils. I know of no source for them other than from a RF board. As you may be aware RF boards in any shape go for a premium. Usually well over $100 and scarce.

Might ask on this forum if anyone has one that they are using to harvest parts from. Otherwise I think you are looking at buying a tech special and they arent cheap on Ebay.

I do not know what the inductance is for any of them other than L41. I have measured it and I do that with the slug tuned even with top of the former.

If your problem is that they do not hold their position have you tried wrapping teflon plumbers tape on the cores and re-inserting them? I find this works much better than rubber bands. Holds them in place and they dont tend to gall or sieze in place.

Yes that was well spent money.I also got one of the PLL board and it came out real nice.$10 EACH.
As i am lucky to have four good working hybrids,three ts830's and one ts520s,this Ebay special has been a good training rig with your help.
If it was not for this forum,i would be up well you know S--- creek with out the paddle.
I don't like to pawn off junk to other hams or anybody else.I would ratter sell it as parts or throw it in the creek.
No we did not talk about the -6 volts,well i had made mention of it,but i guess it was not were you wanted me to test.
You made no mention of a source for coils for the RF board.Do you know the inductance for them.Maybe i could rewind them.
The coils with the bigger slugs have not been a problem like the smaller ones,3.5,7 MHZ.
I do have a L/C from alldigital.
Thanks for pointing that out about the different probes as i did not know that.
I just did a startpage search on the probes and found the pk3 schematic with the three diodes.
Guess i will build the two or buy the two different ones on Ebay.
I see on Ebay there is a PK1 too.
I see they are advertising cougar women on our group site now hi hi.

Yes I have the big schematic as well. Have one laminated and other real dog eared one that I mark on and one brand new in the mailing tube as a spare. Very helpful.

If you have no -6 at audio board then you will have no Receive bias RB1 at RF amp on RF board. You want to turn off Q1 RF amp in transmit mode. You will also have no cutoff bias (TB) for the TIF amp on the IF board. Also will have no AGC action as -6 supplies AGC amp transistor Q10. Also, the -6 is used to back bias the agc detector diodes to set the AGC threshold. So missing it at Audio and IF boards is a big deal. I thought we had talked about it when we discussed S-meter action. Perhaps not. Lot of ground has been covered.

Yes this rig sure is a mess and will present a challenge and as you say a learning experience for you. This is one if on the bench would be no way to bill all the hours you would have in it. I dont work on them any more.

I wrote a pretty detailed primer on why need single diode and multi-diode probe and what characteristics you should look for in a diode, but dont remember what Message number it is. Not sure with this new format if you could ever find it. Things like that probably should go in the files section. Maybe you can try searching on RF probes? It is important to understand that the diode is seeing the peak and what the PIV will be in selecting a diode. We dont care too much about flat frequency response and real precise voltage measuring.

If you can find a germanium signal diode that is what I would opt for. They will give you the best sensitivity. 1n34A, 1n60, 1n270 will all work. Dont use a silicon fast switcher like a 1n914 or 1n4148. They will work but barrier voltage is too high. If you cant find a germanium then a Schottky like a 1n5711 will work. Scotts Elecronics (crystal set parts) state side sells them on his website.

Just remember that you cant get on plate of Driver tube or the control grids of the 6146 finals with a single diode probe. Approx 30 to 35 volts is max and will destroy the diode attempting to measure the RF drive levels at those two locations. I would make a 3 diode probe for the higher RF voltage levels you will want to measure. It wont be good for low levels so you use the 1 diode probe for that. This is why Heath offered the 309C and the PK-3.

To make tracing easier i went and had the TS 830 color schematic blown up to 2x3,a lot better on old eyes to follow.
I took all the voltages from the abbreviation schematic,to make sure i had not missed any on the connectors.
The one we did not discuss was the minus 6 volts.I had it on the counter unit,but not on the audio or IF board.I was able to trace the wire back to the -6 volt switch board and found it had broken off.
After soldering the wire back on the post i now had white noise,if that's what you call it when i turned the rig on
I now have the whole front panel removed to get at the +0.5 switch as three wire's have broken off that switch.
Needed a good cleaning anyway.

I still have very week signal's or high attenuation on all bands.The high bands have higher s-meter reading on the SSG than the lower bands,with 21 MHz being the strongest.

Question
My Rf board is good except for the mixer and ant coils.
Is there any were one can get sub's for these coils.The rubber band trick works ok,but makes it harder to adjust the coils.
Once i get it back together i can go on with the injection steps on the IF board
I tried to get a Rf probe on Ebay for my VTVM but got outbid,so will roll my own.
Which diode would you recommend for a RF probe.

I am not sure on how many owners had this Ebay special before me,but even the wire's are dull in color compared to my other rigs.
The only reason i have not flogged it off,as it makes a good training radio for me to learn on.

Don

Use a low level to inject 8.830 at RIF on IF board and couple output of sig gen thru about a .01uf cap. Nothing more than 5 mv. Also, a couple of the cans will have very little effect on signal level on the S-meter as you turn the core. Do not worry about those at this time. If you get some improvement in S-meter indication suggest you lower the sig gen level and make a 2nd pass. What you are looking for is something that has been grossly mis-tuned that will make IF chain come alive.

If doing IFT alignment does not produce significant improvement in Rx sensitivity then I think time to remove the IF board and do good visual inspection on all the molex pins under magnification and look at all the traces for damage and signs of cobbled repairs. Can have lifted pads and traces, solder bridging, wire jumpers, maybe even a blown trace etc.

I am pretty sure I had you measure Carrier Oscillator and VBT Osc previously and you reported they were to spec. I think we also measured all the DC supply voltages to the board.

We have not yet tried injecting signals in to the IF filters and measuring the output to verify filters are good.

We can do signal injection/tracing next to find where the attenuation is occurring or you can pull board and do good visual. If you have already done that then only thing left (assuming that all necessary signals and DC inputs are present on the board) is to do signal injection/tracing.

I have to trust you when you report back that you have the signals and voltages I ask you to check and that you have the test gear to detect and measure these required inputs and know how to use them. I am not there to witness any of these measurements. I can tell you however it is pretty common for me to hear back from someone I am trying to help that previously reported findings were not correct.

I mean no disrespect it is just a pretty common for this to happen.

I believe you are saying that when you inject 8.830 @500mv from your RF sig gen into the RIF terminal on the IF board you have a loud high frequency tone that you can vary with the audio gain pot (not tunable with the VFO), but the S-meter level is only at S1?

I think we measured RFG at Conn 8 with RF gain pot full CW? It should be 3.6vdc

I think we measured AGC bus voltage at Conn 15? .Need to use nothing less than a 10 meg DMM. It will pull the AGC bus down from 3.6 to close to 3.0vdc or slightly less.

Have you measured these two voltages? Normally if the AGC bus voltage is low the S-meter will be driven up scale with no signal applied unless the S-meter driver circuit is bad.

Have you ever performed the IFT alignment? You can perform the procedure in the maintenance section of the operating manual or the steps in the service manual.

Yes that was well spent money.I also got one of the PLL board and it came out real nice.$10 EACH.
As i am lucky to have four good working hybrids,three ts830's and one ts520s,this Ebay special has been a good training rig with your help.
If it was not for this forum,i would be up well you know S--- creek with out the paddle.
I don't like to pawn off junk to other hams or anybody else.I would ratter sell it as parts or throw it in the creek.
No we did not talk about the -6 volts,well i had made mention of it,but i guess it was not were you wanted me to test.
You made no mention of a source for coils for the RF board.Do you know the inductance for them.Maybe i could rewind them.
The coils with the bigger slugs have not been a problem like the smaller ones,3.5,7 MHZ.
I do have a L/C from alldigital.
Thanks for pointing that out about the different probes as i did not know that.
I just did a startpage search on the probes and found the pk3 schematic with the three diodes.
Guess i will build the two or buy the two different ones on Ebay.
I see on Ebay there is a PK1 too.
I see they are advertising cougar women on our group site now hi hi.

On 23/09/2013 2:30 PM, wagstw46@yahoo.com wrote:

Yes I have the big schematic as well. Have one laminated and other real dog eared one that I mark on and one brand new in the mailing tube as a spare. Very helpful.

If you have no -6 at audio board then you will have no Receive bias RB1 at RF amp on RF board. You want to turn off Q1 RF amp in transmit mode. You will also have no cutoff bias (TB) for the TIF amp on the IF board. Also will have no AGC action as -6 supplies AGC amp transistor Q10. Also, the -6 is used to back bias the agc detector diodes to set the AGC threshold. So missing it at Audio and IF boards is a big deal. I thought we had talked about it when we discussed S-meter action. Perhaps not. Lot of ground has been covered.

Yes this rig sure is a mess and will present a challenge and as you say a learning experience for you. This is one if on the bench would be no way to bill all the hours you

would have in it. I dont work on them any more.

I wrote a pretty detailed primer on why need single diode and multi-diode probe and what characteristics you should look for in a diode, but dont remember what Message number it is. Not sure with this new format if you could ever find it. Things like that probably should go in the files section. Maybe you can try searching on RF probes? It is important to understand that the diode is seeing the peak and what the PIV will be in selecting a diode. We dont care too much about flat frequency response and real precise voltage measuring.

If you can find a germanium signal diode that is what I would opt for. They will give you the best sensitivity. 1n34A, 1n60, 1n270 will all work. Dont use a silicon fast switcher like a 1n914 or 1n4148. They will work but barrier voltage is too high. If you cant find a germanium then a Schottky like a 1n5711 will work. Scotts Elecronics (crystal set parts) state side sells them on his website.

Just remember that you cant get on plate of Driver tube or the control grids of the 6146 finals with a single diode probe. Approx 30 to 35 volts is max and will destroy the diode attempting to measure the RF drive levels at those two locations. I would make a 3 diode probe for the higher RF voltage levels you will want to measure. It wont be good for low levels so you use the 1 diode probe for that. This is why Heath offered the 309C and the PK-3.

Terry

To make tracing easier i went and had the TS 830 color schematic blown up to 2x3,a lot better on old eyes to follow.
I took all the voltages from the abbreviation schematic,to make sure i had not missed any on the connectors.
The one we did not discuss was the minus 6 volts.I had it on the counter unit,but not on the audio or IF board.I was able to trace the wire back to the -6 volt switch board and found it had broken off.
After soldering the wire back on the post i now had white noise,if that's what you call it when i turned the rig on
I now have the whole front panel removed to get at the +0.5 switch as three wire's have broken off that switch.
Needed a good cleaning anyway.

I still have very week signal's or high attenuation on all bands.The high bands have higher s-meter reading on the SSG than the lower bands,with 21 MHz being the strongest.
Question
My Rf board is good except for the mixer and ant coils.
Is there any were one can get sub's for these coils.The rubber band trick works ok,but makes it harder to adjust the coils.
Once i get it back together i can go on with the injection steps on the IF board
I tried to get a Rf probe on Ebay for my VTVM but got outbid,so will roll my own.
Which diode would you recommend for a RF probe.

I am not sure on how many owners had this Ebay special before me,but even the wire's are dull in color compared to my other rigs.
The only reason i have not flogged it off,as it makes a good training radio for me to learn on.

Use a low level to inject 8.830 at RIF on IF board and couple output of sig gen thru about a .01uf cap. Nothing more than 5 mv. Also, a couple of the cans will have very little effect on signal level on the S-meter as you turn the core. Do not worry about those at this time. If you get some improvement in S-meter indication suggest you lower the sig gen level and make a 2nd pass. What you are looking for is something that has been grossly mis-tuned that will make IF chain come alive.

If doing IFT alignment does not produce significant improvement in Rx sensitivity then I think time to remove the IF board and do good visual inspection on all the molex pins under magnification and look at all the traces for damage and signs of cobbled repairs. Can have lifted pads and traces, solder bridging, wire jumpers, maybe even a blown trace etc.

I am pretty sure I had you measure Carrier Oscillator and VBT Osc previously and you reported they were to spec. I think we also measured all the DC supply voltages to the board.

We have not yet tried injecting signals in to the IF filters and measuring the output to verify filters are good.

We can do signal injection/tracing next to find where the attenuation is occurring or you can pull board and do good visual. If you have already done that then only thing left (assuming that all necessary signals and DC inputs are present on the board) is to do signal injection/tracing.

I have to trust you when you report back that you have the signals and voltages I ask you to check and that you have the test gear to detect and measure these required inputs and know how to use them. I am not there to witness any of these measurements. I can tell you however it is pretty common for me to hear back from someone I am trying to help that previously reported findings were not correct.

I mean no disrespect it is just a pretty common for this to happen.

I believe you are saying that when you inject 8.830 @500mv from your RF sig gen into the RIF terminal on the IF board you have a loud high frequency tone that you can vary with the audio gain pot (not tunable with the VFO), but the S-meter level is only at S1?

I think we measured RFG at Conn 8 with RF gain pot full CW? It should be 3.6vdc

I think we measured AGC bus voltage at Conn 15? .Need to use nothing less than a 10 meg DMM. It will pull the AGC bus down from 3.6 to close to 3.0vdc or slightly less.

Have you measured these two voltages? Normally if the AGC bus voltage is low the S-meter will be driven up scale with no signal applied unless the S-meter driver circuit is bad.

Have you ever performed the IFT alignment? You can perform the procedure in the maintenance section of the operating manual or the steps in the service manual.

44844. RE: Extending The Life of Tubes?

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)

Topic: 44833 Message: 44844

Chris:

I can test your 6146 finals for you but need to have some discussion about what that means . My test set is very similar to what you can see on K8CU website. Mine goes to 5KV and is current limited to approx 100ua. I used a microwave oven transformer, capacitor, and rectifier. It cannot hurt your tubes.

I can measure the ua leakage current and mark them on the shield ring with a Sharpie, but not much value to you if you cant repeat test when you reach for them which could be years from now.

I cannot guarantee they will not arc over now and I cannot guarantee they wont 2 or 3 years down road when you reach for them. If they test good now (by my definition of good) very likely they will be OK in RF service if installed when you get them back.

One of the problems is no one knows what the acceptance criteria or test voltage should be. No published data I can find for 6146 tubes. EIMAC has bulletins on hi-potting their high power transmitter tubes that gives the dc test voltage and the acceptable leakage current.

So in addition to not being able to guarantee they would not arc over when you need them here is other thing to think about:

1. There is the round trip packing and shipping cost. I wont charge you to test them.
2. There is the jeopardy from damage/breakage during transit. Even if you heavy bubble wrap the 500 lb gorillas will do their best to break them!
3. What you will know is that per K9TWs acceptance criteria and experience with testing that in 10/2013 your 6146 finals did not have excessive leakage current and were able to hold off typical voltage level that would be seen in KW RF service. You wont know if they have deteriorated when you reach for them. To ameliorate that you could start a program of rotating your spares on an annual basis. You could do a spring tune up and cleaning with a good visual inspection and lube the fan and VFO gear train and rotate the finals.

Here is how I arrived at my test procedure and acceptance criteria. No one has validated this:

What is the approx RF voltage swing at the anode at 100 watts out and assuming 840vdc anode voltage?

840 x .9 x .707 = 535rms rf volts and 535 x 2.828 = 1513 rf volts Peak to Peak. So I add a little to that and use 1600 vdc to simulate the RF swing that the 6146 finals see. I am able to measure the actual rf voltage across the Tank using HP410c and HP453A and it measures very close to 525 volts so the above formula is valid for approximations.

On my test set with the test leads installed and power on at 2000vdc I have approx 7 to 10 ua leakage current. I subtract this base value from any readings I get during the step voltage vs leakage current test.

I connect plus lead to the anode and minus lead the cathode (same as suppressor grid which is physically closest element to the anode) .

1. Start at 1000vdc and record ua leakage.
2. Increase to 1100 vdc and record ua leakage
3. Increase to 1200 vdc and record ua leakage
4. Increase to 1300 vdc and record ua leakage
5. Increase to 1400 vdc and record ua leakage
6. Increase to 1500 vdc and record ua leakage
7. Increase to 1600 vdc and record ua leakage

If tube holds off 1600 vdc I usually see something on the order of 15ua leakage.

At each step I hold it there for a few ,moments and see if the ua leakage is jumping around. I try to see if the leakage is increasing in a linear manner.

If the tube arcs over it will peg the ua meter and I immediately back down the voltage. I try to anticipate arc over and catch it but not easy to do. If meter is flicking at each step not a good sign.

If it arcs over I repeat the test and sometimes it will then be able to hold off 1600vdc. Other times it will arc over again and if it does then I trash it.

So only ones I keep as spares are those who hold off 1600vdc on first or 2nd pass at around 15ua leakage.

I have some that will hold off 2000vdc on first pass. Dont normally test to this level but have done it to see what is the max and have seen one that would hold off 2500vdc.

Not sure what they would see in pulse service?

So let me know what you want to do. Might take off list for details on shipping etc.

You can go to WB4HFN web site where Mark WB0IQK has posted my final board mod under the Kenwood section of the site.

Had a nice discussion about keeping tubes alive on a old timer's round table a few days. The consensus with the old timer's was that tube rigs should be kept on 24/7 to extend their life. I am certain there is a point of diminishing returns with this statement. If one used the radio once per day, or just a couple of time per week would it not be better to shut 'er down for the in between time. There is also the issue of diminishing returns with mains power being consumed versus the cost of new tubes.

I also do not run at greater than 100Watts.

Terry had mentioned some NOS 6146B's were gassy. That is disconcerting. I did not know the were sealed against the base. I guess that is where sweep tubes have the advantage. I have yet to come across a bad NOS tube. However, I have only messed with the small 12AX7 types.

Terry, if we send you tubes can you verify that these babies won't arc over? I wouldn't even mind if you charged me a fee for this. I am thinking of getting a set and putting them

away for a rainy day. I am really enjoying my 520 Sugar -- white noise on CW and all :D I have been working DX on 40m. This is something new to me.

No only metal in the core will change the inductance.

Inductance is related to the permeability of the core material. A vacuum and essentially non-ferrous materials have a permeability of 1.

Brass and aluminum are special cases seen typically at VHF. Work opposite of iron cores. Inductance is reduced as you turn the brass core into the coil.

Sorry I forgot about the Drive and Mixer coils. I know of no source for them other than from a RF board. As you may be aware RF boards in any shape go for a premium. Usually well over $100 and scarce.

Might ask on this forum if anyone has one that they are using to harvest parts from. Otherwise I think you are looking at buying a tech special and they arent cheap on Ebay.

I do not know what the inductance is for any of them other than L41. I have measured it and I do that with the slug tuned even with top of the former.

If your problem is that they do not hold their position have you tried wrapping teflon plumbers tape on the cores and re-inserting them? I find this works much better than rubber bands. Holds them in place and they dont tend to gall or sieze in place.

Yes that was well spent money.I also got one of the PLL board and it came out real nice.$10 EACH.
As i am lucky to have four good working hybrids,three ts830's and one ts520s,this Ebay special has been a good training rig with your help.
If it was not for this forum,i would be up well you know S--- creek with out the paddle.
I don't like to pawn off junk to other hams or anybody else.I would ratter sell it as parts or throw it in the creek.
No we did not talk about the -6 volts,well i had made mention of it,but i guess it was not

were you wanted me to test.
You made no mention of a source for coils for the RF board.Do you know the inductance for them.Maybe i could rewind them.
The coils with the bigger slugs have not been a problem like the smaller ones,3.5,7 MHZ.
I do have a L/C from alldigital.
Thanks for pointing that out about the different probes as i did not know that.
I just did a startpage search on the probes and found the pk3 schematic with the three diodes.
Guess i will build the two or buy the two different ones on Ebay.
I see on Ebay there is a PK1 too.
I see they are advertising cougar women on our group site now hi hi.

Don/Ve2ud

On 23/09/2013 2:30 PM, wagstw46@... wrote:

Yes I have the big schematic as well. Have one laminated and other real dog eared one that I mark on and one brand new in the mailing tube as a spare. Very helpful.

If you have no -6 at audio board then you will have no Receive bias RB1 at RF amp on RF board. You want to turn off Q1 RF amp in transmit mode. You will also have no cutoff bias (TB) for the TIF amp on the IF board. Also will have no AGC action as -6 supplies AGC amp transistor Q10. Also, the -6 is used to back bias the agc detector diodes to set the AGC threshold. So missing it at Audio and IF boards is a big deal. I thought we had talked about it when we discussed S-meter action. Perhaps not. Lot of ground has been covered.

Yes this rig sure is a mess and will present a challenge and as you say a learning experience for you. This is one if on the bench would be no way to bill all the hours you would have in it. I dont work on them any more.

I wrote a pretty detailed primer on why need single diode and multi-diode probe and what characteristics you should look for in a diode, but dont remember what Message number it is. Not sure with this new format if you could ever find it. Things like that probably should go in the files section. Maybe you can try searching on RF probes? It is important to understand that the diode is seeing the peak and what the PIV will be in selecting a diode. We dont care too much about flat frequency response and real precise voltage measuring.

If you can find a germanium signal diode that is what I would opt for. They will give you the best sensitivity. 1n34A, 1n60, 1n270 will all work. Dont use a silicon fast switcher like a 1n914 or 1n4148. They will work but barrier voltage is too high. If you cant find a germanium then a Schottky like a 1n5711 will work. Scotts Elecronics (crystal set parts) state side sells them on his website.

Just remember that you cant get on plate of Driver tube or the control grids of the 6146 finals with a single diode probe. Approx 30 to 35 volts is max and will destroy the diode attempting to measure the RF drive levels at those two locations. I would make a 3 diode probe for the higher RF voltage levels you will want to measure. It wont be good for low levels so you use the 1 diode probe for that. This is why Heath offered the 309C and the PK-3.

Terry K9TW

Terry

To make tracing easier i went and had the TS 830 color schematic blown up to 2x3,a lot better on old eyes to follow.
I took all the voltages from the abbreviation schematic,to make sure i had not missed any on the connectors.
The one we did not discuss was the minus 6 volts.I had it on the counter unit,but not on the audio or IF board.I was able to trace the wire back to the -6 volt switch board and found it had broken off.
After soldering the wire back on the post i now had white noise,if that's what you call it when i turned the rig on
I now have the whole front panel removed to get at the +0.5 switch as three wire's have broken off that switch.
Needed a good cleaning anyway.

I still have very week signal's or high attenuation on all bands.The high bands have higher s-meter reading on the SSG than the lower bands,with 21 MHz being the strongest.
Question
My Rf board is good except for the mixer and ant coils.
Is there any were one can get sub's for these coils.The rubber band trick works ok,but makes it harder to adjust the coils.
Once i get it back together i can go on with the injection steps on the IF board
I tried to get a Rf probe on Ebay for my VTVM but got outbid,so will roll my own.
Which diode would you recommend for a RF probe.

I am not sure on how many owners had this Ebay special before me,but even the wire's are dull in color compared to my other rigs.
The only reason i have not flogged it off,as it makes a good training radio for me to learn on.

On 15/09/2013 8:10 AM, wagstw46@... wrote:

Don

Use a low level to inject 8.830 at RIF on IF board and couple output of sig gen thru about a .01uf cap. Nothing more than 5 mv. Also, a couple of the cans will have very little effect on signal level on the S-meter as you turn the core. Do not worry about those at this time. If you get some improvement in S-meter indication suggest you lower the sig gen level and make a 2nd pass. What you are looking for is something that has been grossly mis-tuned that will make IF chain come alive.

If doing IFT alignment does not produce significant improvement in Rx sensitivity then I think time to remove the IF board and do good visual inspection on all the molex pins under magnification and look at all the traces for damage and signs of cobbled repairs. Can have lifted pads and traces, solder bridging, wire jumpers, maybe even a blown trace etc.

I am pretty sure I had you measure Carrier Oscillator and VBT Osc previously and you reported they were to spec. I think we also measured all the DC supply voltages to the

board.

We have not yet tried injecting signals in to the IF filters and measuring the output to verify filters are good.

We can do signal injection/tracing next to find where the attenuation is occurring or you can pull board and do good visual. If you have already done that then only thing left (assuming that all necessary signals and DC inputs are present on the board) is to do signal injection/tracing.

I have to trust you when you report back that you have the signals and voltages I ask you to check and that you have the test gear to detect and measure these required inputs and know how to use them. I am not there to witness any of these measurements. I can tell you however it is pretty common for me to hear back from someone I am trying to help that previously reported findings were not correct.

I mean no disrespect it is just a pretty common for this to happen.

Don/Ve2ud

--- In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Don

I believe you are saying that when you inject 8.830 @500mv from your RF sig gen into the RIF terminal on the IF board you have a loud high frequency tone that you can vary with the audio gain pot (not tunable with the VFO), but the S-meter level is only at S1?

I think we measured RFG at Conn 8 with RF gain pot full CW? It should be 3.6vdc

I think we measured AGC bus voltage at Conn 15? .Need to use nothing less than a 10 meg DMM. It will pull the AGC bus down from 3.6 to close to 3.0vdc or slightly less.

Have you measured these two voltages? Normally if the AGC bus voltage is low the S-meter will be driven up scale with no signal applied unless the S-meter driver circuit is bad.

Have you ever performed the IFT alignment? You can perform the procedure in the maintenance section of the operating manual or the steps in the service manual.

Terry K9TW

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry

Now i remember what i said about loud but no s-meter reading,it is this test i did and now i have redid it with the 8.8830 injection at conn 6

I got S1 meter reading with 500 mv injection in con 6 and same on the RF board con 5 pin 2

Don

So trusting that the audio board is working as it should and can process the output of the Product Detector, then the problem now is very weak Marker and very weak off air signals and low or no S-meter indication. Dont worry about weak moni at this point.

So this is place I would use RF sig generator and split the problem. Is it on the IF board or the RF board (or both but not likely). If you want to work back from the Audio Board then I would inject 8.830 mhz into the RIF terminal on the IF board and see if you can hear it loud and good S meter indication. If you can then move on to the RF board. If you cannot get back and we can talk about signal injection/tracing on the IF board.

Inject 8.830mhz at Conn 6 on IF board. You dont need any modulation. -73dBM/50uv should give approx S6. -53dBm/500uv should give approx S9. -33dBm/5mv should give approx +20 over.

I also found this is a previous post by w5rkl.

The external VFO DIN socket has an embedded switch and controls the internal VFO's power. When the external VFO is not plugged into the 530 then the DIN socket embedded switch closes, allowing power to be applied to the internal VFO.

It looks like there is lots of information here in old posts, trick is to know what to look for.

--- In ts-520_820_530_830@yahoogroups.com, <va7deo@...> wrote:

Thanks. I was looking at the service manual.

I'll guess that the VFO control pin is what switches from the internal to external VFO. I'll have a look at the schematics to see if I can verify that.

Topic: 44830 Message: 44848

The problem Mike, seems to be that if any one of the resistors fails, or changes in value
you tend to get a runaway situation. My final was never run at such a high cathode current,
but that was exactly what happened. The whole idea of using such small resistors in a hot
environment with and appreciable current flowing is simply not good design practice.
Kenwood's are pretty good but they were by no means perfect even in the late 1970's.

Topic: 44830 Message: 44851

Clifford:

You need to think about this a little more. You are not seeing tube run away when cathode resistors begin to fail. You are seeing false high plate current if you were to have a domino failure of the cathode resistors.

6146 plate current is not dependent on whether you have 5 ohms or 20 ohms in the cathode. Plate current is determined by the Screen Grid voltage and the negative operating bias on the control grids. As long as you still have nominal -60vdc bias on the control grids no way for tubes to run away.

This false high plate current occurs anytime you remove a resistor from a parallel combination because the cathode resistance now goes up and for a given amount of plate current the IR drop across the remaining resistors goes up. Your plate current meter is a ua movement configured with a series meter multiplier resistor to measure the IR drop across the cathode resistors. It is a voltmeter. Maximum voltage it can read is E = IR or E = 350ma x 5 ohms = 1.75vdc. That is 0.40vdc across the meter movement and 1.35vdc across the multiplier. Each of the 35 meter divisions represent .05vdc across the meter movement.

It is normal for cathode resistors to age high. I often find them around 7 to 8 ohms. This is a conservative failure as it causes the IR drop to be higher for a given plate current and the OP thinks he is loading to higher plate current than what he really is.

With rig loaded to 200ma plate current the IR drop across the 5 ohm cathode resistance is .200 x 5 = 1.0vdc. If the cathode resistors have aged high to 8 ohms then you have an IR drop of .200 x 8 = 1.6vdc. The plate current meter will now read 320ma and not the 200 ma that is actually flowing.

In a TS520 with two 10 ohm cathode resistors in parallel for 5 ohms and 200ma plate current the IR drop will be E=IR or E = .200 x 5 = 1.0vdc. Now for some reason one resistor fails open in the scenario you describe. The 200ma plate current does not run away. The 6146 finals do not care if there is 10 or 5 ohms in the cathode. What happens is you now have twice the the ohmic value of cathode resistance or 10 ohms. Now E=IR or E = .200 x 10 = 2.0vdc. The plate current meter circuit that is designed to measure a maximum of 1.75vdc is now slammed against the peg and the OP thinks his tubes are glowing red.

I think you need to rethink the KW hybrid design. The plate current metering circuit works just fine.

Terry K9TW

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

The problem Mike, seems to be that if any one of the resistors fails, or
changes in value
you tend to get a runaway situation. My final was never run at such a
high cathode current,

but that was exactly what happened. The whole idea of using such small resistors in a hot
environment with and appreciable current flowing is simply not good design practice.
Kenwood's are pretty good but they were by no means perfect even in the late 1970's.
Zl1BDA.

44852. RE: RE: Re: Cathode resistors as fuses

From: <wagstw46@...>
Topic: 44830 Message: 44852

I have an error.

The .05vdc per meter graduation is across the meter circuit (series multiplier and meter movement) and not the meter movement itself. 1.75vdc / 35 = 0.05 vdc. So for each division on the meter you need 0.05 vdc IR drop across the cathode meter shunts which the "voltmeter" is measuring.

So if you are reading 320 ma on IP position (hope you are not) then there is 32 x .05 = 1.6vdc being dropped across your cathode resistors. I = E/R or I = 1.6vdc/5ohms = .320 or 320ma. The Ip "voltmeter" is measuring 1.6vdc at 200 ma.

There is actually 0.0114vdc per each of the 35 graduations on the meter movement itself. So for 200ma there is 1 vdc IR drop across the cathode resistors. The Ip "voltmeter" is measuring this 1.0 vdc. The meter movement sees .0114 x 20 or .288vdc and the series multiplier has 1.0 - .288 = 0.712vdc across it.

Sorry but easy for errors to creep in whenever doing calcs.

Point remains losing cathode resistor does not result in final plate current increase or runaway. It results in false high Ip indication due to higher IR drop across a now higher cathode resistance.

Terry .

Maximum voltage it can read is E = IR or E = 350ma x 5 ohms = 1.75vdc. That is 0.40vdc across the meter movement and 1.35vdc across the multiplier. Each of the 35 meter divisions represent .05vdc across the meter movement.

It is normal for cathode resistors to age high. I often find them around 7 to 8 ohms. This is a conservative failure as it causes the IR drop to be higher for a given plate current and the OP thinks he is loading to higher plate current than what he really is.

With rig loaded to 200ma plate current the IR drop across the 5 ohm cathode resistance is .200 x 5 = 1.0vdc. If the cathode resistors have aged high to 8 ohms then you have an IR drop of .200 x 8 = 1.6vdc. The plate current meter will now read 320ma and not the 200 ma that is actually flowing.

In a TS520 with two 10 ohm cathode resistors in parallel for 5 ohms and 200ma plate current the IR drop will be E=IR or E = .200 x 5 = 1.0vdc. Now for some reason one resistor fails open in the scenario you describe. The 200ma plate current does not run away. The 6146 finals do not care if there is 10 or 5 ohms in the cathode. What happens is you now have twice the the ohmic value of cathode resistance or 10 ohms. Now E=IR or E = .200 x 10 = 2.0vdc. The plate current meter circuit that is designed to measure a maximum of 1.75vdc is now slammed against the peg and the OP thinks his tubes are glowing red.

I think you need to rethink the KW hybrid design. The plate current metering circuit works just fine.

Terry, can you do a little write up on how to modify the final and/or meter circuitry to protect the movement during a flash over?

Thanks,
Chris KQ6UP

Chris:

I can test your 6146 finals for you but need to have some discussion about what that means . My test set is very similar to what you can see on K8CU website. Mine goes to 5KV and is current limited to approx 100ua. I used a microwave oven transformer, capacitor, and rectifier. It cannot hurt your tubes.

I can measure the ua leakage current and mark them on the shield ring with a Sharpie, but not much value to you if you cant repeat test when you reach for them which could ! be years from now.

I cannot guarantee they will not arc over now and I cannot guarantee they wont 2 or 3 years down road when you reach for them. If they test good now (by my definition of good) very likely they will be OK in RF service if installed when you get them back.

One of the problems is no one knows what the accept! ance criteria or test voltage should be. No published data I can find for 6146 tubes. EIMAC has bulletins on hi-potting their high power transmitter tubes that gives the dc test voltage and the acceptable leakage current.

So in addition to not being able to guarantee they would not arc over when you need them here is other thing to think about:

1. There is the round trip packing and shipping cost. I wont charge you to test them.
2. There is the jeopardy from damage/breakage during transit. Even if you heavy bubble wrap the 500 lb gorillas will do their best to break them!
3. What you will know is that per K9TWs acceptance criteria and experience with testing that in 10/2013 your 6146 finals did not have excessive leakage current and were able to hold off typical voltage level that would be seen in KW RF service. You wont know if they have deteriorated when you reach for them. To ameliorate that you could start a program of

rotating your spares on an annual basis. You could do a! spring tune up and cleaning with a good visual inspection and lube the fan and VFO gear train and rotate the finals.

Here is how I arrived at my test procedure and acceptance criteria. No one has validated this:

What is the approx RF voltage swing at the anode at 100 watts out and assuming 840vdc anode voltage?

840 x .9 x .707 = 535rms rf volts and 535 x 2.828 = 1513 rf volts Peak to Peak. So I add a little to that and use 1600 vdc to simulate the RF swing that the 6146 finals see. I am able to measure the actual rf voltage across the Tank using HP410c and HP453A and it measures very close to 525 volts so the above formula is valid for approximations.

On my test set with the test leads installed and power on at 2000vdc! I have approx 7 to 10 ua leakage current. I subtract this base value from any readings I get during the step voltage vs leakage current test.

I connect plus lead to the anode and minus lead the cathode (same as suppressor grid which is physically closest element to the anode) .

1. Start at 1000vdc and record ua leakage.
2. Increase to 1100 vdc and record ua leakage
3. Increase to 1200 vdc and record ua leakage
4. Increase to 1300 vdc and record ua leakage

5. Increase to 1400 vdc and record ua leakage
6. Increase to 1500 vdc and record ua leakage
7. Increase to 1600 vdc and record ua leakage

If tube holds off 1600 vdc I usually see something on the order of 15ua leakage.

At each step I hold it there for a few ,moments and see if the ua leakage is jumping around. I try to see if the leakage is increasing in a linear manner! .

If the tube arcs over it will peg the ua meter and I immediately back down the voltage. I try to anticipate arc over and catch it but not easy to do. If meter is flicking at each step not a good sign.

If it arcs over I repeat the test and sometimes it will then be able to hold off 1600vdc. Other times it will arc over again and ! if it does then I trash it.

So only ones I keep as spares are those who hold off 1600vdc on first or 2nd pass at around 15ua leakage.

I have some that will hold off 2000vdc on first pass. Dont normally test to this level but have done it to see what is the max and have seen one that would hold off 2500vdc.

Not sure what they would see in pulse service?

So let me know what you want to do. Might take off list for details on shipping etc.

You can go to WB4HFN web site where Mark WB0IQK has posted my final board mod under the Kenwood section of the site.

OK remove last statement

Meter circuit is not just fine from standpoint if cathode shunts blow open it does present an open cathode and the cathode will rise toward SG voltage and will climb to over 100vdc and that represents jeopardy for the panel meter.

When I said it was fine I meant in reference to the voltmeter method, its accuracy and if the shunts drift high it puts rig in a conservative position due to high false plate current readings.

The design does not result in tube run away if cathode resistors experience a domino failure. If they did that I would agree design was severely flawed.

Terry K9TW

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Clifford:

You need to think about this a little more. You are not seeing tube run away when cathode resistors begin to fail. You are seeing false high plate current if you were to have a domino failure of the cathode resistors.

6146 plate current is not dependent on whether you have 5 ohms or 20 ohms in the cathode. Plate current is determined by the Screen Grid voltage and the negative operating bias on the control grids. As long as you still have nominal -60vdc bias on the control grids no way for tubes to run away.

This false high plate current occurs anytime you remove a resistor from a parallel combination because the cathode resistance now goes up and for a given amount of plate current the IR drop across the remaining resistors goes up. Your plate current meter is a ua movement configured with a series meter multiplier resistor to measure the IR drop across the cathode resistors. It is a voltmeter. Maximum voltage it can read is E = IR or E = 350ma x 5 ohms = 1.75vdc. That is 0.40vdc across the meter movement and 1.35vdc across the multiplier. Each of the 35 meter divisions represent .05vdc across the meter movement.

It is normal for cathode resistors to age high. I often find them around 7 to 8 ohms. This is a conservative failure as it causes the IR drop to be higher for a given plate current and the OP thinks he is loading to higher plate current than what he really is.

With rig loaded to 200ma plate current the IR drop across the 5 ohm cathode resistance is .200 x 5 = 1.0vdc. If the cathode resistors have aged high to 8 ohms then you have an IR drop of .200 x 8 = 1.6vdc. The plate current meter will now read 320ma and not the 200 ma that is actually flowing.

In a TS520 with two 10 ohm cathode resistors in parallel for 5 ohms and 200ma plate current the IR drop will be E=IR or E = .200 x 5 = 1.0vdc. Now for some reason one resistor fails open in the scenario you describe. The 200ma plate current does not run away. The 6146

finals do not care if there is 10 or 5 ohms in the cathode. What happens is you now have twice the the ohmic value of cathode resistance or 10 ohms. Now E=IR or E = .200 x 10 = 2.0vdc. The plate current meter circuit that is designed to measure a maximum of 1.75vdc is now slammed against the peg and the OP thinks his tubes are glowing red.

I think you need to rethink the KW hybrid design. The plate current metering circuit works just fine.

Chris here is the mod. I recently within last month showed the calcs on how to size the MOVs. Should be easy to find if this new format still supports searches.

Chris:

I can test your 6146 finals for you but need to have some discussion about what that means . My test set is very similar to what you can see on K8CU website. Mine goes to 5KV and is current limited to approx 100ua. I used a microwave oven transformer, capacitor, and rectifier. It cannot hurt your tubes.

I can measure the ua leakage current and mark them on the shield ring with a Sharpie, but not much value to you if you cant repeat test when you reach for them which could ! be years from now.

I cannot guarantee they will not arc over now and I cannot guarantee they wont 2 or 3 years down road when you reach for them. If they test good now (by my definition of good) very likely they will be OK in RF service if installed when you get them back.

One of the problems is no one knows what the accept! ance criteria or test voltage should be. No published data I can find for 6146 tubes. EIMAC has bulletins on hi-potting their high power transmitter tubes that gives the dc test voltage and the acceptable leakage current.

So in addition to not being able to guarantee they would not arc over when you need them here is other thing to think about:

1. There is the round trip packing and shipping cost. I wont charge you to test them.
2. There is the jeopardy from damage/breakage during transit. Even if you heavy bubble wrap the 500 lb gorillas will do their best to break them!
3. What you will know is that per K9TWs acceptance criteria and experience with testing that in 10/2013 your 6146 finals did not have excessive leakage current and were able to hold off typical voltage level that would be seen in KW RF service. You wont know if they have deteriorated when you reach for them. To ameliorate that you could start a program of rotating your spares on an annual basis. You could do a! spring tune up and cleaning with a

good visual inspection and lube the fan and VFO gear train and rotate the finals.

Here is how I arrived at my test procedure and acceptance criteria. No one has validated this:

What is the approx RF voltage swing at the anode at 100 watts out and assuming 840vdc anode voltage?

840 x .9 x .707 = 535rms rf volts and 535 x 2.828 = 1513 rf volts Peak to Peak. So I add a little to that and use 1600 vdc to simulate the RF swing that the 6146 finals see. I am able to measure the actual rf voltage across the Tank using HP410c and HP453A and it measures very close to 525 volts so the above formula is valid for approximations.

On my test set with the test leads installed and power on at 2000vdc! I have approx 7 to 10 ua leakage current. I subtract this base value from any readings I get during the step voltage vs leakage current test.

I connect plus lead to the anode and minus lead the cathode (same as suppressor grid which is physically closest element to the anode) .

1. Start at 1000vdc and record ua leakage.
2. Increase to 1100 vdc and record ua leakage
3. Increase to 1200 vdc and record ua leakage
4. Increase to 1300 vdc and record ua leakage

5. Increase to 1400 vdc and record ua leakage
6. Increase to 1500 vdc and record ua leakage
7. Increase to 1600 vdc and record ua leakage

If tube holds off 1600 vdc I usually see something on the order of 15ua leakage.

At each step I hold it there for a few ,moments and see if the ua leakage is jumping around. I try to see if the leakage is increasing in a linear manner! .

If the tube arcs over it will peg the ua meter and I immediately back down the voltage. I try to anticipate arc over and catch it but not easy to do. If meter is flicking at each step not a good sign.

If it arcs over I repeat the test and sometimes it will then be able to hold off 1600vdc. Other times it will arc over again and ! if it does then I trash it.

So only ones I keep as spares are those who hold off 1600vdc on first or 2nd pass at around 15ua leakage.

I have some that will hold off 2000vdc on first pass. Dont normally test to this level but have done it to see what is the max and have seen one that would hold off 2500vdc.

Not sure what they would see in pulse service?

So let me know what you want to do. Might take off list for details on shipping etc.

You can go to WB4HFN web site where Mark WB0IQK has posted my final board mod under the Kenwood section of the site.

Had a nice discussion about keeping tubes alive on a old timer's round table a few days. The consensus with the old timer's was that tube rigs should be kept on 24/7 to extend their life. I am certain there is a point of diminishing returns with this statement. If one used the radio once per day, or just a couple of time p! er week would it not be better to shut 'er down for the in between time. There is also the issue of diminishing returns with mains power being consumed versus the cost of new tubes.

I also do not run at greater than 100Watts.

Terry had mentioned some NOS 6146B's were gassy. That is disconcerting. I did not know the were sealed against the base. I guess that is where sweep tubes have the advantage. I have yet to come across a bad NOS tube. However, I have only messed with the small 12AX7 types.

Terry, if we send you tubes can you verify that these babies won't arc over? I wouldn't even mind if you charged me a fee for this. I am thinking of getting a set and putting them away for a rainy day. I am really enjoying my 520 Sugar -- white noise on CW and all :D I have been working DX on 40m. This is something new to me.

See message 43912 for how I sized the MOVs for SG protection. There is an error in last sentence about rigs primary fuse ratings. Check your manual for proper size for 120vac primary fusing.

If you do anything at all suggest you install the 3 silicon diodes across the cathode resistors to limit maximum IR drop across them to approx 2vdc.

Thanks Joe..and the rest of the thread.

Tonight the switched worked. overtime and on 80 meters as well as 20 meters. Either I have an intermindant or perhaps i didnt give the heater enough time to warm up. But now that its working, its hard to trouble shoot. If i have to go in for another reason, I'll check the relay and get it cleaned up..or replaced. The good news is I went and got some more canned air for the occasion and it was on sale for 10 bucks for 3 cans. so now i am well stocked.

Thanks everybody.

Subject: [TS-520_820_530_830] 520s send/rec switch not working

Hi Group, sorry if this has been posted already, but i am having problems find things here with the new group look.

After many, many years my send/rec switch stopped operating.(TS-520S) It fires the relay occasionally. It started when i tried to tune on 80 meters for the first time in a long time. Click, and nothing. Switched back down to 20 and it worked intermediately. So from past experience, would this be the switch, the relay, or power to the relay? .....Possibly the band switch??

I havent begun to even look at it yet tonight..too late to start. I will try keying the relay via the mic tomorrow, and a few other things. I wanted to get a post going so i'll have some input to think on while I look at the schematics.

Thanks

Steve

I agree with this as vacuum tubes are considered a consumable item. Reducing the voltage also means keeping check on the power supply and capacitors. I use audio amps that have push pulls of 6BQ5s and I find 8BQ5s work well and are more robust.

Subject: [TS-520_820_530_830] Extending The Life of Tubes?

Had a nice discussion about keeping tubes alive on a old timer's round table a few days. The consensus with the old timer's was that tube rigs should be kept on 24/7 to extend their life. I am certain there is a point of diminishing returns with this statement. If one used the radio once per day, or just a couple of time per week would it not be better to shut 'er down for the in between time. There is also the issue of diminishing returns with mains power being consumed versus the cost of new tubes.

I also do not run at greater than 100Watts.

Terry had mentioned some NOS 6146B's were gassy. That is disconcerting. I did not know the were sealed against the base. I guess that is where sweep tubes have the advantage. I have yet to come across a bad NOS tube. However, I have only messed with the small 12AX7 types.

Terry, if we send you tubes can you verify that these babies won't arc over? I wouldn't even mind if you charged me a fee for this. I am thinking of getting a set and putting them away for a rainy day. I am really enjoying my 520 Sugar -- white noise on CW and all :D I have been working DX on 40m. This is something new to me.

For those of us that have only been on this site less than a year,
could you take a few minutes and give us some history of this great
effort. When did it start, who started it, and just a little
history. Maybe a short profile of the Hams that have put in the work
to make it work so well. Great effort and Thanks for your service.

Greeting Group!

Well, as you figured...I'm one of the new co-owners. I've got some big shoes to fill. I will endeavor
to do my best. This is a great group! Let's PLEASE keep it that way. I will thank Gordon-n6wk,
Mike-w5rkl, and Terry-k9tw for their knowledge and expertise, they were, and still are, a big help
to me and, many others..TNX!

My background: EX Radioman USCG, first ticket 1977 and still wb7uqu. Most of my adult life was spent as a professional
firefighter, firefighter/paramedic and later Fire Lieutenant with the City of Tacoma WA Fire Dept. I retired after 33 years of service
I still am on a rather steeplearning curve as far as in depth diagnostics and radio theory...but getting better. That's all for now.

QRU?

Yes, the radio was dropped during shipping. The back heatsink was bent and cracked. When I went to tune my G5RV, the finals went dark after about three seconds of key down (output power dropped to near zero). I have never popped finals in any rig in 26 years of ham radio.

The seller blamed me for popping the finals and even went as far as to suggest that I dropped the radio. However, UPS has a record of dropping the radio, and they are cutting him a check for $100. Now he finally believes that I didn't drop the radio.

So there remains a question in my mind. Why is this thing popping finals so easily since this radio does not have a reputation for it? Is the protect circuitry working? Did something get damaged when it was dropped? I can do the work myself, but it would be nice to have a professional technician take a look at the radio as a third party.

I am trying to join the FT-107M group, but it has been several days and I have not heard anything. Buying this radio was the original reason I pulled the TS-520S into service because I wanted to sell it, and I forgot what was wrong with the 520sugar. I have too many radios now :D However, I fell in love with the TS-520S receiver, and I will probably end up selling my FT-101E in its place when all the dust settles.

Thanks es 73,

Chris KQ6UP

My guess is that enough force that would bend and crack the heat sink could very well have ripped off the mounting studs of one or more of the PA transistors or cracked the ceramic material of the transistor body. If either one of those happens it doesn't surprise me that the transistors went poof very quickly. It might also have torn some of the flat leads off of the PA transistors as well. I would also be very suspicious that there might be other internal damage to the radio as well.

Why is UPS only paying him $100? Sounds like he did not insure it for the full sales price.

You'd have a better case if the finals had gone dead while transmitting into a dummy load, though.

The manual does say that the finals are protected against high SWR by shutting down the drive. I assume that you are using a tuner with the G5RV and you start with a low level of output power, adjust the tuner, and then increase your drive level, correct?

73,

Bill

Correct. He did not. He also did a terrible job of packing the item. The
box was not much bigger than the radio. He claimed it was "double boxed",
but there was no more than an inch of packing peanuts between the first and
second box. Not my idea of a double boxed package. However, this point is
now moot since UPS is claiming responsibility for the damage.

Yes, you are correct. I was hesitant to divulge this at first, but I had
to show my cards at some point.

Yes, this is the best way to handle this, but considering there is a
protection circuit and the radio is not known for being a final popper.
The radio repairman Charles Turner agrees the finals should have not been
popped in three seconds even into a shorted or open load. The protect
circuitry should have done its job.

A Versa Tuner II was inline. In hindsight it would have been better to
test a damaged rig into a dummy load -- however this rig is intended to be
a field day rig, and better it pop sooner while not be babied than blowing
several months later at field day at the hands of a nOOb.

HI BART WOULD U LIKE TO SELL ME SOME OF THAT ANGEL HAIR WIRE?? PLEASE LET ME KNOW THANKS JIMMY.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Well,

My #42 came in...good thing it is a 1600ft spool...LOL (smallest I could find).

If you need some, let me know.

Boy oh boy...it is "Angel hair" and with my fat fingers.....:)

On the serious side, what if the windings overlap or cross, does it make a difference?

Hi Jimmy:

Apparently you have lost an L41. How did that happen?

I recently posted all the L41 winding data over on QRZ under the Boatanchor technical forum helping a fellow over there who lost one.

Need a steady hand and magnifier head set. You may have to wind 3 to get 1 good one!

In the factory-shipped configuration for a new TS-520S, there was absolutely no space between the inside skin of the outer shipping box and the outside skin of the inner box (the box with the string ties on top). The inner box containing the TS-520S simply slipped into the ever-so-slightly-larger outer box. Thus, the shipper of your TS-520S actually packed it better than the factory- assuming - and this is a big if... he used the correct inner box with the front and rear Styrofoam protective end caps. If he did use the correct inner box with the Kenwood factory-supplied end caps, then the problem is due to poor UPS Ground handling, which unfortunately is a relatively common occurrence.

Best of luck.

Yes, I would not ship UPS as I have seen the damage they cause. The radio that was damaged was an FT-107M. The TS-520S was brought out to test before selling, and I decided to keep it. That is what led me to start posting on this group again after a 4 year hiatus. Just looking forward to this nightmare with this idiotic seller to end. Now he is saying he shouldn't have to pay for it's repair. He is saying UPS should repair it, but he did not insure it -- so I think he is out of luck. He is getting $100 from them that's it. He is still responsible ultimately to make it right.

Chris,

As you probably know, UPS Ground automatically insures all shipments for $100 at no extra cost to the shipper. The shipper was certainly derelict in this situation for not insuring it for the full selling price, not only for your protection, but his as well. This is extremely irresponsible on his part, and really a no-brainer. If you paid for the FT-107M via PayPal, I would think you could submit a complaint.

BTW... I've got a great story on the FT-107M. E-mail me off list and I will elaborate!

You might check the ebay buyer protection plan. It might cover the return shipping costs, too.

It probably would have, but the system is forcing me to settle by sending
him the radio for a full refund. I had escalated this to a claim, but it
is automatically resolved by shipping it to him. At this point I just want
this nightmare to be over. I will never by a radio again on ebay without
stipulating six inches of packing material and full insurance. No friggen
UPS either. This guy has been such a cheap jerk from the get go. Just
thinking of what to add to my negative review. I am probably going to just
put "Glad this nightmare is over." There is not much he can say to that.
Ugh!

Thanks guys!

I wrote ebay and told them the rating on the sellers shipping fee is worthless to me. I have never been really gouged on shipping cost oher than Ebay taking a piece of the action. I have however had many items damaged in shipment and if not damaged the carton smashed in or torn open. It is almost a crap shoot anymore if the item will survive the journey.

I told Ebay I would like to see a far better category and that would be how well did the seller pack the item or make it an additional rating category. It is amazing how poorly most items are packed by the seller. Either too dumb or too cheap or combo of both.

Today whether it is Post Office, UPS or Fed Ex I always double box with a 2 to 3 inch crush zone on all 6 sides with the item heavy bubble wrapped in the inner box. In the crush zone I use high density foam or peanuts (no wadded up newspaper). I also try to use heavier weight cardboard boxes. All of this cost more but I would prefer to pay extra for a professional packing job than have the rig damaged. I have had people willing to split the cost of packing correctly.

You cannot ship a hybrid circuit board in a padded shipping envelope or a flat rate box with a little wadded up newspaper. I have more than one broken or severely bowed board from this penny pincher method.

A guy shipped me a Variac in a flat rate box with newspaper around it. Needless to say it didnt make it. Also got a soaking wet and deteriorated box with a Heath Cantenna set inside a bed of wadded up newspaper. Of course when box took a blow the side of the paint can was severely dented and the lid popped off and the oil spilled out! What an idiot. He agreed to give me half my money back after much argument.

Could go on but you get the idea. Oh by the way no response from Ebay.

Topic: 44872 Message: 44891

Cases like this are very unfortunate. Its part of what gives buying and selling on ebay a bad reputation. There are still honest, decent sellers out there. I have to admit that I have bought some stuff on ebay that was so poorly packed I was surprised they arrived undamaged. I suspect that most of the sellers on ebay do not know how to properly pack items. The carriers are not kidding when they specify 3 to 4 inches of packing material on all sides.

I'd hold off on the negative feedback until after I receive my refund, though :)

One lesson here is that if the rig arrives with obvious damage, don't even plug it in. You can't tell what type of internal damage might have occurred. Just get your refund.

Glad you will be getting your refund.

73,

Bill

Subject: Re: [TS-520_820_530_830] OT: Vintage Radio Tech in SoCal?

It probably would have, but the system is forcing me to settle by sending him the radio for a full refund. I had escalated this to a claim, but it is automatically resolved by shipping it to him. At this point I just want this nightmare to be over. I will never by a radio again on ebay without stipulating six inches of packing material and full insurance. No friggen UPS either. This guy has been such a cheap jerk from the get go. Just thinking of what to add to my negative review. I am probably going to just put "Glad this nightmare is over." There is not much he can say to that.
Ugh!

Thanks guys!

UPS usually will pick up the tab to ship it back since it was damaged by
them.
Doesn't hurt to call them and ask. They have done it for me.

That dude owed you a full refund. I would have opened a claim on that
one. He could have taken it up with the carrier.

Terry,

The guy who shipped the Variac in the flat rate box might have been me. Did the flange break off? That was back when I was a lot less experienced in shipping stuff.

I wrote ebay and told them the rating on the sellers shipping fee is worthless to me. I have never been really gouged on shipping cost oher than Ebay taking a piece of the action. I have however had many items damaged in shipment and if not damaged the carton smashed in or torn open. It is almost a crap shoot anymore if the item will survive the journey.

I told Ebay I would like to see a far better category and that would be how well did the seller pack the item or make it an additional rating category. It is amazing how poorly most items are packed by the seller. Either too dumb or too cheap or combo of both.

Today whether it is Post Office, UPS or Fed Ex I always double box with a 2 to 3 inch crush zone on all 6 sides with the item heavy bubble wrapped in the inner box. In the crush zone I use high density foam or peanuts (no wadded up newspaper). I also try to use heavier weight cardboard boxes. All of this cost more but I would prefer to pay extra for a professional packing job than have the rig damaged. I have had people willing to split the cost of packing correctly.

You cannot ship a hybrid circuit board in a padded shipping envelope or a flat r! ate box with a little wadded up newspaper. I have more than one broken or severely bowed board from this penny pincher method.

A guy shipped me a Variac in a flat rate box with newspaper around it. Needless to say it didnt make it. Also got a soaking wet and deteriorated box with a Heath Cantenna set inside a bed of wadded up newspaper. Of course when box took a blow the side of the paint can was severely dented and the lid popped off and the oil spilled out! What an idiot. He agreed to give me half my money back after much argument.

Could go on but you get the idea. Oh by the way no response from Ebay.

No it was not you Bill. I dont know about lack of experience relative to packing items for shipment. I dont know of any training program for it.

I do know it is going hundreds if not thousands of miles and will be thrown, dropped, items stacked on top of it by people and machines who are mindlessly handling millions of packages with no thought to what is inside.

I had a UPS truck loader tell me once that he and the other high school drop outs that are loading trucks at 0300 in the morning and see a carton with "fragile and this side up" ;labels all over it gets the "treatment". You can use your imagination what that means.

I do know a little about common sense. What I know about that is that there is no such thing......only common practice!

In the factory-shipped configuration for a new TS-520S, there was
absolutely no space between the inside skin of the outer shipping box
and the outside skin of the inner box (the box with the string ties on
top). The inner box containing the TS-520S simply slipped into the
ever-so-slightly-larger outer box. Thus, the shipper of your TS-520S

actually packed it better than the factory- assuming - and this is a big if... he used the correct inner box with the front and rear Styrofoam protective end caps. If he did use the correct inner box with the Kenwood factory-supplied end caps, then the problem is due to poor UPS Ground handling, which unfortunately is a relatively common occurrence.

Best of luck.

Here in VK, most of the couriers will not insure, I just received a Tl922 cost me $300+ for freight, the seller double boxed, 100mm peanuts and even placed 6mm masonite around the enire unit, only to have the courier break 2 feet. Had I known this I would have done the 32 hour return trip to pick it up. A lot of the couriers are gorrilas and dont know how to lift or use proper lifting equipment

Dave

VK5PDL

Cases like this are very unfortunate. Its part of what gives buying and selling on ebay a bad reputation. There are still honest, decent sellers out there. I have to admit that I have bought some stuff on ebay that was so poorly packed I was surprised they arrived undamaged. I suspect that most of the sellers on ebay do not know how to properly pack items. The carriers are not kidding when they specify 3 to 4 inches of packing material on all sides.

I'd hold off on the negative feedback until after I receive my refund, though :)

One lesson here is that if the rig arrives with obvious damage, don't even plug it in. You can't tell what type of internal damage might have occurred. Just get your refund.

Glad you will be getting your refund.

73,

Bill

It probably would have, but the system is forcing me to settle by sending him the radio for a full refund. I had escalated this to a claim, but it is automatically resolved by shipping it to him. At this point I just want this nightmare to be over. I will never by a radio again on ebay without stipulating six inches of packing material and full insurance. No friggen UPS either. This guy has been such a cheap jerk from the get go. Just thinking of what to add to my negative review. I am probably going to just put "Glad this nightmare is over." There is not much he can say to that.
Ugh!

Thanks guys!

Well all is moot now. After fighting me for nearly a week he has offered to send me a full refund. However that will leave me high and dry for the price of the return shipping. I hate paying for other people's idiocy. Boo!

Chris,

As you probably know, UPS Ground automatically insures all shipments for $100 at no extra cost to the shipper. The shipper was certainly derelict in this situation for not insuring it for the full selling price, not only for your protection, but his as well. This is extremely irresponsible on his part, and really a no-brainer. If you paid for the FT-107M via PayPal, I would think you could submit a complaint.

BTW... I've got a great story on the FT-107M. E-mail me off list and I will elaborate!

Yes, I would not ship UPS as I have seen the damage they cause. The radio that was damaged was an FT-107M. The TS-520S was brought out to test before selling, and I decided to keep it. That is what led me to start posting on this group again after a 4 year hiatus. Just looking forward to this nightmare with this idiotic seller to end. Now he is saying he shouldn't have to pay for it's repair. He is saying UPS should repair it, but he did not insure it -- so I think he is out of luck. He is getting $100 from them that's it. He is still responsible ultimately to make it right.

Hello Gordon,

I hope this finds you well & your health problems are in abeyance. Thank you for your many years of service and the maintenance of your web-site as well. You are as much a resource as the group and web-site are. Thanks as well for taking the time and effort to find the right fit for the new co-owner. Joe, good luck and best wishes for long service in your new endeavor. I will keep you both in my prayers. The Great Master will keep us all in fine fettle. It is nice to know that you will stay on as moderator. This is, and has been, one of the best groups I've seen and been a part of. I didn't realize how good 'til I joined some others... sheesh! Keep fit and take best care of one of our "resources"... you.

May God bless and keep you,

mjsyn(mike)

That was going to be my field day rig. However, now that I am feeling all Kenwoody -- would a TS-130S be a good FD rig? I need a radio with a very strong front end because we are often running CW/SSB at the same time on the same band. Rugged too for the n00b to abuse.

Well gang, I got tired of waiting around for a "Twins" cable to show-up so I modified the sets using the 1800 series connectors from HRD. Digikey has them but maybe a back-order. Here are the Digikey part numbers listed below. You will need order two of each line item. You will not have to change any of the metalwork on your radios to install the new style connectors. No new holes to drill, etc. Except for the connectors themselves, the sets will remain stock.The new connectors are held in the chassis using the hardware supplied with them and two metal strips cut and drilled from stainless steel stock from Ace Hardware. Easy to mount and you can revert back the the old connector if the real cable shows up later. Send me a message for some pictures since this forum doesn't allow picture attachments which is kind of dumb with what we do to these Hybrid rigs.

P-1616A-ST(51)-ND PLUG
P-1616A-C(50)-ND CASE
S-1616A(09)-ND SOCKET
P-1616BA(09)-ND SOCKET RETAINER

What I really need now is a real and detailed diagram of the original Kenwood Twins transceive cable and NOT what's depicted in the manuals which is pretty lacky. If a straight-through cable is made and deployed, the relay inside the receiver won't do anything when the transmitter is keyed.

Regards,

Jim L.

---In ts-520_820_530_830@yahoogroups.com, <pmarkavage@...> wrote:

The R-599/T-599 interconnection cable used the Hirose 1300 series type of connectors (round pins). These were discontinued many years ago. Your best bet is to use the current Hirose 1600 series of connectors (flat pins). However, you would also have to change out the connector on the R-599 and T-599 to match the cable connectors. Doable stuff, but not trivial.

As far as uploading Pictures.. take that up with Yahoo.
They are the ones preventing it!

Topic: 44803 Message: 44902

Ok anyone with a CW narrow filter in their TS-520 get this much wide band white noise on a quiet band or dummy load?

Video: http://youtu.be/Fv1RLn_Ws_I

Thanks,
Chris KQ6UP

44903. Re: [TS-520_820_530_830] RE: transceive cable for kenwood twins

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-25 08:39:28 UTC
From: Guy Morgan
Topic: 24774 Message: 44903

First of all, thanks to Gordon for his work as owner of this excellent resource. WRT pictures etc., there is a files section where such things can be put and then referenced from the list. Most if not all lists I subscribe to block pictures or any other attachments from being sent direct to the list as attachments are a fertile source of “nasties” which none of us want to receive!

As far as uploading Pictures.. take that up with Yahoo.
They are the ones preventing it!

Well gang, I got tired of waiting around for a "Twins" cable to show-up so I modified the sets using the 1800 series connectors from HRD. Digikey has them but maybe a back-order. Here are the Digikey part numbers listed below. You will need order two of each line item. You will not have to change any of the metalwork on your radios to install the new style connectors. No new holes to drill, etc. Except for the connectors themselves, the sets will remain stock.The new connectors are held in the chassis using the hardware supplied with them and two metal strips cut and drilled from stainless steel stock from Ace Hardware. Easy to mount and you can revert back the the old connector if the real cable shows up later. Send me a message for some pictures since this forum doesn't allow picture attachments which is kind of dumb with what we do to these Hybrid rigs.

P-1616A-ST(51)-ND PLUG
P-1616A-C(50)-ND CASE
S-1616A(09)-ND SOCKET
P-1616BA(09)-ND SOCKET RETAINER

What I really need now is a real and detailed diagram of the original Kenwood Twins transceive cable and NOT what's depicted in the manuals which is pretty lacky. If a straight-through cable is made and deployed, the relay inside the receiver won't do anything when the transmitter is keyed.

Regards,

Jim L.

The R-599/T-599 interconnection cable used the Hirose 1300 series type of connectors (round pins). These were discontinued many years ago. Your best bet is to use the current Hirose 1600 series of connectors (flat pins). However, you would also have to change out the connector on the R-599 and T-599 to match the cable connectors. Doable stuff, but not trivial.

Congratulations Joe on your appointment as a new group co-owner. I'm sure you will do great. Thank you for your kind words.

A Coast Guard Radioman? I was a Navy Radioman for 22 years, retired as an RMC(SW) in Dec 1988.

Dear Gurus !!

I have a TS 511S and a HP23A (Heath Power supply)- has anybody ever tried to use HP23A to fire TS511S since most of the voltages are meeting the requirements of TS 511S.

I would appreciate any help whatsoever in this direction as I am about to use HP23A to fire TS511S.

Seeking help, please note- it is impossible to find a matching PS 511S in India and to get it from US or Japan- is out of budget option

Kshitij,
Hello. I have been looking for a PS for you but have not been able to find one. I do not know about the HP23A. I do not know enough about my own 511S to be of any help. Have been saving it for this winter as a project. I have a few unfinished projects to complete and did not want to start another until my bench is cleared. Perhaps someone here has more experience with the 511S and can help you.

Thanks a ton !!! I am still hopeful- but this attempt is just to start using TS511S- otherwise it will be a unit with all dry capacitors and out of tolerance resistors.

Warm Regards and in our language- 73

Hi Gordon,

Have you tried sending them the schematic via email? I've done that in the past with Sarah Gore, International Crystals, and they were able to determine the value they needed to make the crystals.

Gordon;

Looking at the schematic it looks like parallel resonance to me based on the components it the feedback loop. So they will want to know the load capacitance that the circuit places across the crytal.

You can try using your digital LCR bridge and measure the capacitance across the crystal in the circuit.

If they cannot tell by looking at the circuit I would buy one designed for about 30pf load. Then if too high can pad it down.

Terry K9TW

Terry,
upon checking just now, My Transmitter is an early version and has a
different circuit.

Here is my circuit. Hard to read, but best I have for now.
http://www.n6wk.com/CE-100V/ce-100v-crystal.gif
I just sent a copy of this to International Crystal as well

BTW, you -do- have the schematic and operating manual for this, yes?
I've got a low-res one, got it off the internet somewhere if you don't.
DON'T have the PS-511 schematic, but the plug wiring diagram for the
xcvr in the operating manual has enough information to get going on.

You will need a 2-wire cable for the fan connection. It's just AC mains
voltage, 117VAC or whatever passes for that amount of voltage in your
area. 110, 115, 117, 120, somewhere around that. Need that or you'll
cook your finals and all the parts near them.

For the rest, you need several voltages. 12.6V AC for the filaments
first off, pins 5 and 8 on the power connector. The power switch is on
pins 2 and 3. The PS-511 power switch connects through the power cable
to those two pins, and when you apply power to the power supply, the
TS-511 power gets switched on as well through that connection.

Pins 12 and ground (looks like you can use either of pins 6 or 9 for
it), are for the external speaker connection.

Like all the other TS-5XX series radios, the rest is pretty much
straight-forward.

You require an earth ground of course, and a chassis ground to tie the
two boxes together at the cabinet for a signal ground. (And also to
keep from shocking the snot out of yourself.)

Final grid bias, -C, is -90VDC and is on pin 1 of the connector. To be
dead-certain you got that, from pin one to the chassis ground you
should have NEGATIVE NINETY VOLTS DC.

The B+ voltages are next. There is +150VDC on pin 4, +210VDC on pin 7,
+300VDC at pin 10, and +800VDC on pin 11. (All are measured with
respect to chassis ground, of course.)

It appears that the power cable for the TS-510 / PS-510 pair would also
work for your TS-511, at least get you a starting point to work from.

(Comparing the schematics makes me 99% certain of it, but if there is something I missed, please to correct it.)

That ought to get you started. I highly recommend that you shield the power connector cable between your power supply and the TS-511, and make sure both chassis are grounded to the same potential and to earth ground. The voltages and currents in here can kill you quicker than quick if you get caught in a ground loop. You can use the shield braid from the power supply cable to tie the chassis both together at the wing-nut ground lug.

Do be cautious about potentials on the cases if your power supply is the 3-prong sort and is tied to the outlet ground. If your rig has an independent ground (a ground rod outside the window just for the shack for instance) and the house mains ground is NOT bonded together with it with a low-resistance strap between them, then there might (probably will) be potential between the shack independent ground and the outlet mains ground. A potentially deadly ground. (Pun of course intended.)

This is a concern that transcends what kind of radios you have. Grounding is an art and a science all of its own. You should look into making certain there are no stray voltages waiting to take you out of the picture first time you flip the switch, or touch the chassis while it is plugged into the mains.

If anyone sees any flaw in that, please point it out. Infallible I ain't and never claimed to be. I would rather not hear about someone headed for the Ghats prematurely, or even just in need of a keg of Ganges water.

If you have that schematic, you've got almost all you need. If not, I found it at

http://www.wb4hfn.com/KENWOOD/Manuals/TS-511S%20Operations%20Manual.pdf

and you can get it there (in case you don't have it, though I suspect you do). (If someone has a better one, please upload it to the group file site, just for completeness' sake? AND the PS-511 as well, if you have it?

We have the model 510 stuff in there, and several others, and it's not as if we're out of room in the group allotment, either. If space does ever get low, well, that could be the first to go to get room for something better.

Until then, I don't see any reason why not to archive it. If there are good and sufficient reasons not to keep these files, as determined by the group admin folks, then that's good enough for me, no arguments here.

But the availability of these documents is VERY low, even in poor quality, and I think clean copies here would result in more good copies elsewhere , before it is over.

(The Kenwood site doesn't list it in their downloads, by the way, either of the 511 items.)

OK now I dont see feed back loop from plate of osc tube with any reactive components so it may be a series resonant xtal? If so, then no need to specify CL. Maybe there is enough shown here for International to tell?

On reflection my suggestion to measure capacitance with your LCR isnt good.

What you really need is a VNA or Impedance Analyzer so you can measure the X at crystal frequency. Then very easy to calculate the CL. X= .159/CL x F. Measure F with counter and measure X with VNA and solve for CL.

The new Aim VNA2180 is just the ticket for measuring crystal parameters. Goes for around $1500. Of course you could go to Ebay and shop for a HP4294. I think there may be one or two for around $30,000.00! An HP8753 VNA can be had for less than $10,000.00! If I find out you have either on your bench I will be mad!

I would love to have the VNA2180. It is a 2 port VNA. I think Phil Salas AD5X just reviewed it for QST.

If International cant help you then you have justification for adding nice piece of test gear to your bench. Might want to email AIM and see if the single port 4170 (around $500) can measure crystal parameters.

Then I would know where I could borrow one! I have had VNA on Xmas list for couple of years, but so far Santa has not been able to spell VNA!

Gordon;

Looking at the schematic it looks like parallel resonance to me based on the components it the feedback loop. So they will want to know the load capacitance that the circuit places across the crytal.

You can try using your digital LCR bridge and measure the capacitance across the crystal in the circuit.

If they cannot tell by looking at the circuit I would buy one designed for about 30pf load. Then if too high can pad it down.

I have a TS520 that I used nearly every day for nearly 40 years, I repaired a few little failures in the past by replacing componants like transistors diodes and capacitors.
NOW I had a flashover around the screen pin on one 6146 socket that destroyed a few resistors and a choke in the 210 V line. The material around the pin is burned , charred badly, and I don't turst it any more. I triedf scraping away at it with an Exacto knife but am sure it will be trouble in the future.
I have decided to keep it on and use it as a receiver only. My plan is to remove the three tubes, and disconnect the HV output connections at the rectifier board and secure each of the wire ends with an insulating sleeve. Anyone see a problem with that arrangement?

I use Mozilla Thunderbird e-mail client for reading the individual e-mail posts in the Yahoo Groups I subscribe to. Since I don't access the posts through a browser, no problem with any pop up ads here - in terms of the individual posts.

Nevertheless, what we're experiencing, especially regarding the ads, is the impact of the relatively-new CEO Marissa Mayer. Remember, she was a long-time executive at Google, and her job is to increase Yahoo's ad revenue which was seriously in the tank prior to her arrival. She's bound to ruffle feathers across the board, as what I've heard about her management style is: "take no prisoners."

There's absolutely zero chance of Yahoo killing Neo in favor of the Classic format. I suppose we could use the mailman.qth.net list server, but then we'd just have a mail reflector, and we'd lose all of the great features and storage capability of Yahoo groups.

John, K8JD,

Count your blessings, then count your equipment.

I use my TS-830S as a "Second" Receiver only. Bad Driver Tube.
I use my 1977 Heath HW-8 100% of the time,
on 20M and 40M QRP/CW only.

Having a "Second" receiver has advantages.
1) I can check the other band for lower noise or higher activity,
without retuning my "First" transceiver.
2) I can check the "First" tranceiver's signal quality.
3) Sometimes, when the HW-8 just can not pull-in a signal ,
I switch in the Kenwood and listen on the better "Second" Receiver.
4) The "Second" receiver can have different Antenna, and hear something that the "Main" does not. I use a pair of Long-Wires, so I can do this. Once I have the call sign right, I look up the Callers Bio on QRZ, and from there I can fill-in the blanks during a QSO with QSB, QRN, QRM.

Eventully, I will replace the Kenwood Driver and put it on the air.
But the Kenwood does make a Quiet, Great "Cadillac" of a "Second" Receiver.

Hi Glen, swapping a tube is a lot simpler problem than repairing or replacing a HV flashed, burnt to charcoal final amp board !
I thought long and hard about trying to complete this repair. I already spent a few hours tracing thru the schematic and following wiring bundles through the rig to isolate the problem.
It would be nice to have a quality ham band receiver even though it has no WARC bands or 160M, FOR FREE, since my newer TS440 has been doing most of the work in the shack for the last 10 years anyway. The 520 was usually connected to my 80M dipole and I monitored the SKCC freq on that band for activity while I hopped bands with my TS440s.

Topic: 44915 Message: 44931

It may take a bit of filing (or a screw up type hole cutter) But personally I would replace the Octal sockets with Ceramic types. I do this as a matter of course in all the high powered tube audio gear I repair as they are VERY prone to flash over. probably because the 6L6 and 6V6 had the anode on pin3!!!
As an example a P/P KT88 amp I repaired a couple of years ago had a peak voltage of well
over 1,000 volts between pins 3 and 2!!
I can safely say that I have NEVER had any problems with Ceramic bases.
Makes you very grateful that top cap anodes are standard for TX tubes though!

If it were me, I sure would get a replacement board and get the radio fully operational again.

Lee, w0vt

----- Original Message -----

Hi Glen, swapping a tube is a lot simpler problem than repairing or replacing a HV flashed, burnt to charcoal final amp board !

I thought long and hard about trying to complete this repair. I already spent a few hours tracing thru the schematic and following wiring bundles through the rig to isolate the problem.
It would be nice to have a quality ham band receiver even though it has no WARC bands or 160M, FOR FREE, since my newer TS440 has been doing most of the work in the shack for the last 10 years anyway. The 520 was usually connected to my 80M dipole and I monitored the SKCC freq on that band for activity while I hopped bands with my TS440s.

44933. RE: Re: [TS-520_820_530_830] salvaging a TS520

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-26 10:45:29 UTC
From: <wagstw46@...>
Topic: 44915 Message: 44933

If Mr. Davidson has a final board as opposed to octal sockets and point to point wiring as the early TS520s had he can have a lot of damage to repair. Not very likely he had a failure between tube socket pins on the final board.

Sounds to me like he had a 6146 arc over. Normally when this occurs 900vdc is applied to the suppressor grids and the cathode resistors are the only components that get damaged.

However, if the arc over occurs between anode and control grid then he has a serious problem. 900vdc has been applied to the FG (final grid) line which provides the operating bias and control bias to the finals.

Now you have very heavy current flowing thru L3 choke and back to the RF board to the ALC amp transistor, to the bias pot, thru divider resistors and finally back to the -C supply on the HV rectifier board. A torturous path that does not like to see 900vdc and very high current. Most if not all these components in the path will be destroyed.

It is also possible that this 900vdc may have been applied to the ALC bus thru the ALC transistor collector path and if that occurred then the TIF amp on the IF board is gone as well.

In short this is a very damaging event and very hard to find everything that has been hurt.

I have repaired several of these failures including on the TS830 and it is not fun. Burned boards, burned molex connectors, blown choke and resistors, ALC transistor blown off the board, bias pot burned open, TIF amp mosfets blown etc.

Look at the mods for a TS530 and you will see a recommendation to install a MOV on the FG line. People had the mistaken belief that the FG line was getting hit by lightning and so the proposed fix was to install a MOV. It wasnt lightning it was Final tube arc over.

Take a few moments and read the "FEEDBACK" section of Yahoo Groups and you will find that many Yahoo Group members, not just from this group, are complaining to Yahoo about this mess:

http://yahoo.uservoice.com/forums/209451

I've already voiced my displeasure through their FEEDBACK section.I honestly do not know what Yahoo was thinking when they did this! It's obvious to me they didn't think of the members first.

There is no "service" that is free. Every service has a cost. It may not be in terms of currency.

I dont have to pay for satellite TV or cable TV I can choose to view "free" off air TV, but it comes with a price to me.

I know if I dont like the "service" I am free to use another.

I wonder if everyone exercised that right what Yahoo would do? I bet they might care if no one was watching the advertising.

44944. V06B diodes - finally heard from the vendor.

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-27 00:08:00 UTC
From: Wes Will
Topic: 44755 Message: 44944

Order has been placed. Fifty diodes, quite possibly all he had.

I have requests from

Mac Haszard 10
"Ron" 10
Joseph Stiles 24

And I want four of them, which leaves two to send to Terry W.

The cost including postage and the fees for currency conversion came to ?7.50 which at the rate I got was US $12.33.

!2.33 / 50 is close enough to a quarter apiece as to make it silly to do the math. That's $2.50 each and an SASE for Mac and Ron, and Joe owes me the SASE and $6.

I will send Terry's to him as soon as I get him to give me an address, or he sends me an SASE.

The email address I use for paypal stuff is the same addressee part as I use here, wwill but at a different domain, clearwave dot com (to hopefully at least make the Yahoo Spam-spiders at least work for getting the information).

My mailing address is the station location one (small town in Illinois, zip code 62966, for verification that you have the right address) on the FCC license site. I suspect everyone knows how to look that up using my call sign.

I should have the diodes in roughly a week, he will be dropping them into the Royal Post in about twelve hours at a guess, allowing for the time difference.

Send the envelopes whenever you like,

BUT WAIT UNTIL YOU GET THE DIODES IN-HAND

before dropping any spare change in the pot.

44954. Bird question

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-27 23:04:51 UTC

Hi All,

Not a Hybrid question but I figure plenty of you would have bird meters on your bench.

I have in my collection a 75-250H element that looks genuine and from what I could see it has never been opened (until I looked at it). Under the label written with a Sharpie is "250H - 0.74". Using this element in a 43 gives me full scale 100W rather than 250W. I'm surprised to find a genuine element marked 250 that only reads 100. Has anyone seen anything like this before?

I wonder if that is because the 75-xxx elements are for the 4307 and are designed for 75 ohm lines.

Hi William,

I thought of that but I couldn't find anything in my Bird catalog
regarding 75 ohm meters or elements. However after your post I
managed to find the manual for the 4307 and right there in the
specifications it lists the 75-250H slug. Problem solved!

Thanks for your help

Lou:

You might try contacting Bird at Ohio facility at 866-695-4569 or go to their website and type question into their on-line ASK BIRD - FAQ forum.

They use to repair or replace any element for $50, but it has been several years since I dealt with them.

Lou,

A Bird 75-250H element is 75 ohms and intended to be used in a 75 ohm watt meter such as the Bird 4307. It looks just like the familiar 50 ohm meter.

The impedance mismatch between the 75-250H slug and your 50 ohm Bird is the likely cause of your inaccurate reading.

Craig,
You might want to get on the net this afternoon
and put a question asking that. I keep a list on
my web site, but I don't show anyone up your direction.

Here is the list that I have.
http://wb4hfn.com/KENWOOD/Articles/Kenwood_Hybrid_Repair.pdf

<LarryTkc@...>

If you use Yahoo Groups and hate the new crappy/bloated format, there is
a fix if you use Firefox.

With Firefox open, go to http://ehibbert.org.uk/extension/install.html
and click on the link to install. Firefox will give a few security
warnings and then close and reopen.

Jeff, WA4ZKO (who happens to be an IT professional) gave me the link and
is familiar with the author. It's safe and it works.

Some more info at http://wiki.modplugin.org/Main_Page

44967. Kenwood Net Update (Sept 29, 2013)

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-09-29 18:44:20 UTC
From: Mark Gilger
Topic: 44967 Message: 44967

The Saturday□s net on 40 meter had 21 stations
checking in under Excellent band
conditions. There were 6 new check-ins, WA4RVD,
KC2MKI, K4GEW, VE2UD, N3FZP, and W8RMV. Out of those, there was:

```
2 running TS-520(x)
1 running TS-530(x)
4 running TS-820(x)
6 running TS-830S
0 running TS-900

I was running my TS-940. The rest were running
non hybrids of one model or another.
```

The Sunday□s 20 meter net had 13 stations
checking in under poor band conditions. Out of those, there was:

```
3 running TS-520(x)
0 running TS-530(x)
3 running TS-820(x)
2 running TS-830S

I was running my TS-940. Seems everyone today was
running a solid state radio of one type or another.
```

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

```
If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.
```

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins

November 2012, Saturday☐s, net total = 47, Sundays total = 20
December 2012, Saturday☐s, net total = 74, Sunday☐s total = 70
January 2013, Saturday☐s, net total = 93, Sunday☐s total = 87
February 2013, Saturday☐s net total = 103, Sundays total = 87
March 2013, Saturday☐s, net total = 112, Sunday☐s total =39
April 2013, Saturday☐s net total = 52, Sunday☐s total = 29
May 2013, Saturday☐s net total = 45, Sunday☐s total = 50
June 2013, Saturday☐s net total = 30, Sunday☐s total = 27
July 2013, Saturday☐s net total = 63, Sunday☐s total = 41
August 2013, Saturday☐s net total = 82, Sunday☐s total = 50
September 2013, Saturday☐s net total = 66, Sunday☐s total = 54 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Enjoying the heck out of my new to me TS-520. Just curious -- how do I know if I am getting enough air flow across my 6146s? I just found six new final tubes at an antique store for $20, but I just want to make my finals last as long as possible since this is a commodity item. Feels like the fan case itself is the warmest part. Any of you guys have an IR thermometer that can measure it? I am running the RTTY contest this afternoon, and that sure does a good job of warming the radio with its 100% duty cycle.

Thanks es 73 de KQ6UP

I hope you are not running the 520 at full power on RTTY, not a good thing.

Make sure the fan blades and shroud are clean of dust. Dust can collect rather quickly on the fan blades which causes air flow to be reduced.

Unplug the 520, wait for the HV capacitors to discharge (about 1 minute or is good), remove the top and bottom covers, remove the cover over the final amplifier, and use compressed air and/or canned air to remove dust collection in the final amplifier.

You can have plenty of air flowing in the final enclose but if the tubes have a coating of dust/dirt then the heat will not radiate from the tube's glass envelope. Clean the final amplifier including the tubes, fan blades, and shroud to ensure maximum air flow. Also, do not stack gear along the sides, along the rear, and on top of the 520. This is a common mistake done by many inexperienced hams. Stacking equipment along the sides, rear, and top of the 520 restricts if not blocks the air flow. While stacking your gear together may "Look good", it's can significantly reduce air flow through the gear.

I was running it at 100W for short exchanges. I can imagine a long winded QSO would melt the radio down. What power is recommended for RTTY on the TS-520S? I have the radio clear of stuff, it is about 5" from the wall. I hope that is not an issue. The cage is really clean as I don't think this radio was used very much at all before it died, and/or the original owner went SK. The radio had a clipped lead that fell across the circuit traces; that ruined the balanced modulator. After putting new diodes in her, she is running like a champ. So the radio probably just set for years. It looked brand new when I bought it.

However, I will make it at bi-annual chore to clean it out. It wasn't too hot. I measured 114degF after a couple of minutes to cool down.

Chris,

I have run a LOT of RTTY in my day, mostly rag chewing, but never would run a tube rig over 50% while running it. That would probably mean 50W or less on the TS-520S. If you need more power to "do the deed", you need an amp of some sort. I don't even run "more modern" solid state rigs at 100% as you WILL lose finals that way. Same rule, more power needed, get an amp. The Kenwood 870S is likely an exception to that rule and seemed to tolerate 100%, but I didn't do it. I hope one of the experts will chime, but that's been my rules since the day of the teletype machine in 1972, HI.

I hate to add to my last topic with a different topic. But I am having problems finding the post button. Is it me or is this new format a problem for everybody.

I just came into a 530s. there is a 28MHZ mod that i would like to rid myself of. looks obvious on the surface. a 2 position switch and 4 wires making and breaking some wires going to the VFO board. Anybody know if there are more mods to be on the look out for, maybe some that are not as obvious as a switch and bell wire being strung here and there. The digital display will also blank out from time to time, either when band switching or just tuning across the dial on some bands.

I am looking for info on the 530s including how to do an alignment, etc..the basic stuff. but like I said before I am having problems navigating this forum now.
So far it seems to tune up on 20m but not so much on 40m. made some contacts, VFO seems to be on target, audio is good. Anything to look for that 530s are known for? My Other rig is the 520s

again thanks for the input guys

Topic: 44440 Message: 44974

Hey Terry and everyone:

Sorry this took me so long, I was waiting on parts for my antenna and my AT-230 to arrive in the mail.

I tuned my TS-520 into a dummy load, using the AT-230 as a wattmeter and SWR meter. This is what I observed.

80 meters: Load just about fully meshed, CAR value: 5, 210 ma, 100 watts
40 meters: Load fully meshed, CAR value: 2.75, 210 ma, 80 watts
20 meters: Load 3/4 to meshed, CAR value: 5, 220 ma, 60 watts
15 meters: CAR value: 2.75, 210 ma, 80 watts
10 meters: Load 1/2, CAR value: 4, 210 ma, 80 watts.

I tuned into the center of the band, for voice, on each band.

I noticed that in general, when I keyed the 520 up, the needle for ma would sit at about 240 or 250 ma and then slowly drop off to 210ma on average. I also noticed I had to readjust the bias control for 60ma when I began this whole thing. It was correct the other day, but changed for some reason.

I got all of the stray RF in my shack under control and I checked my antenna and got it to about 5:1 SWR with a nice torroid on it to choke the stray RF. I got a 59 signal report from SW Washington (I am in SW Idaho). I noticed that my tuner won't match the antenna at all on 40 meters or 20 meters, but will match on 15 and 10. I don't know if that is because of an issue with the radio, or the tuner itself, but it was an observation. I get a better SWR on 40 when I am using my antenna without the tuner. In fact, the ham in Washington couldn't hear me at all when I was passing through the tuner, but gave me the 59 without the tuner.

I opened the radio and visually inspected the components you, Terry, suggested. Nothing looks burned, the coils are still shiny and bright and none of the caps looked like they popped, everything, visually, looks clean.

What should I do now?

OK sorry for the confusion. I am clearly confused on who I am taking to at this point and what the problem is. I dont think we discussed yet how to measure/test the fixed padder caps in any rig. I think we last left off with asking you to load test your rig on each

band and not just 40 and 20 meters and reporting back the results?

Terry K9TW

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

I was referring to checking and replacing the padder caps and the other items you described the other day. Brain was helping me tune my TS-520 and the discussion was about complications with that. You mentioned in a couple of previous posts that you were talking about a TS-830. I was concerned there was some confusion about what model of Kenwood was experiencing the issues described in this thread. If they all work the same, I'll get those padder caps tested and look at the other items referred to in your previous post.

I hope that's not more confusing, hehe. Brian knows better than I do and was able to explain the problems better than I could.

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

I am exactly sure what you are asking. If you are asking about how to load a TS520 that has no Tune Ip indication to get that initial plate current dip and is it different than a TS-830 then answer is no difference other than limiting the plate current to 200ma.

Some people with lots of experience load in CW mode. Some do this as they have a good understanding of what is going on and the pre-cautions using this method.

Others do it because the Tune position of their rig quit years ago and too lazy to fix it or dont know how to fix it.

I typically do not teach new folks to load in CW.

However if your rigs Tune position is out and you cannot get that initial plate current dip then you can do it by reducing the Car Level pot to minimum and with meter in Ip position Flip to Send and slowly bring the Car Level up to something under 100ma. Have to be careful because Ip can jump very high pretty quickly with very little more opening of the pot.

When you get say around 80ma to 100ma then adjust the plate Tune capacitor for a dip or minimum in plate current and then unkey the rig. Now ready to use the RF relative power position of the panel meter or your external wattmeter to start coupling load. Flip to Send and alternately adjust Plate Load and Plate Tune controls for max relative power on your RF meter position or approx 100 watts output on your wattmeter. Unkey the rig.

Watching the Ip meter flip to send again and if you are reasonably close to 200ma Ip you are done and ready to operate CW or SSB.

WIth a good Tune position I recommend you follow the instructions in your TS520 manual. Only confusing step is peaking the Drive which says to adjust for maximum meter deflection and everyone and I mean everyone asks "what maximum"? The ALC black box maximum or the meter full scale maximum. As I think I told you black box is meaningless at this step but OK to just peak Drive control at max range on it.

After you get that initial plate current dip in Tune mode then all the Kenwood instruction manuals direct you to load by alternately adjusting :Load and Tune controls for max RF relative power. If you have an external wattmeter leave meter in Ip and load for approx 100 watts out without exceeding 200ma.

Subject: RE: Re: [TS-520_820_530_830] New Ham, Tuning issues

Brian:

No problem with using a Key to load the rig. Just not necessary when bench testing a rig. The 830 manual contributes to this when early on they tell you to connect dummy load or antenna and connect a Key and then flip to Send and check resting plate current. However they fail to tell you to press the Key or close the slider if a straight Key. Later under Transmission section under CW header they tell you again to install a Key. Poorly written.

When you turn the Plate Load cap control CW off the full CCW position and you see the RF output power on the wattmeter go down do you then immediately adjust the Plate Tune capacitor to try to bring the RF output power back up?

Anytime the Load cap is moved open or closed you need to make a slight adjustment with the Tune capacitor to restore the tank to resonance. What happens when you do this?

Typically once the reactance of the Plate Load capacitor is close to the impedance of the load (antenna or dummy load) opening the plates (CW) any more usually does not result in anymore RF output on the wattmeter. You reach a point where opening the plates more does not result in coupling any more load. The final tubes just cannot supply any more RF Line current to the Tank.

There is no doubt that loading on 40 meters into a 50 ohm dummy load you should not be at maximum RF output with the Plate Load cap full CCW (plates fully meshed). As you suggest it is not "normal". You know that from your own TS-830.

As I mentioned this is indicative of bad fixed padder caps that are switched in on the lower bands. The reason that this is necessary is if they installed an air variable capacitor that had the necessary high level of capacitance on the lower bands it would then have a minimum capacitance with the plates completely open that would be far too high to function on higher bands. 10 meters is the biggest challenge for the designers. Same for the Plate Tune capacitor.

If you get time it would be good to see if it loads normal on 15 and 10 meters. I would try loading on all the bands and make a chart of how it behaves. Where does the plate Load cap end up for approx 100 watts output at 200ma Ip.

One other thing you should look at if comfortable is the main RF plate choke and the small VHF choke at a right angle at its base and the rf bypass cap at its base. If these show signs of overheating then will need to be replaced. The by pass cap can actually physically split the case open.

Need to have rig unplugged and let set for awhile to led bleeders discharge the HV filter caps. Then remove PA cage cover. Then connect ground jumper from top of plate choke and ground for a few seconds. Now safe to use a good flashlite and inspect these items.

I would also look at both capacitor shaft couplers at the PA cage and make sure screws are tight. Can also watch the travel and make sure full open and full close align with markings on the front panel.

Hi Terry:

Ah ha. I am a CW op so I always have had a key plugged in (but no mic). Anyway, with a key plugged in you don't get any output with the alternate procedure without closing the key for obvious reasons. I've been so used to how the radio responded when I switched over from tune to CW with a key connected that I ended up thinking the key was necessary. My bad. For me the long procedure from the manual works fine since I always have the key connected and normally have the radio in VOX mode (to save wear on the send switch) but I have a better understanding now. Thank you. I will also study the diagram to try to better understand the relationship between the load capacitor and antenna load.

This will also help Jason since I took him through the long procedure from the manual that uses a key. He can just unplug his keyer and will be able to move from tuning to loading once he has the drive and plate a resonance (peaked and dipped) without all of the additional gyrations.

Questions: This still leaves Jason's TS-520's issue with load. Even though I was using the long procedure with the key, I think the results are still accurate. He is getting a maximum output of 70w at 200ma with the load at min (fully CCW) and reducing the load capacitance (increasing the load/turning load CW) actually reduces his output. This isn't normal, right? I can simulate this on my TS-830 but it pains me. If I intentionally turn the load up too much, output falls off as I increase the load. So...I think in Jason's TS520 it is as if even at maximum capacitance (minimum load) he doesn't have enough to balance against the 50 ohm dummy load---resonance is off the minimum end of the load. Does that sound like a reasonable conclusion? Is the next step for us to try the tune up procedure on all bands and report back (your 10m suggestion from before) or is there something else that we should check first?

Thanks,
Brian (and Jason)

Subject: RE: Re: Re: [TS-520_820_530_830] RE: New Ham, Tuning issues

You dont need the key or vox or any of the gyrations you are putting your self thru to load your TS830.

The reason Ip indicates approx 60ma when you switch from Tune to CW mode is that you have the plates meshed on the Plate load cap and you are shunting the RF current around the dummy load and circulating it in the Tank.

It is OK to crack the Plate Load control open a little at initial loading so you can see 70 or 80 ma or so if that helps you.

At this point with plates fully meshed you have maximum capacitance and lowest capacitive reactance so the RF current in the tank is going to like to flow thru the plate load cap and not thru the dummy load. Sometime look at formula for Xc and you will see it is an inverse relationship. It will help you understand what I am telling you.

OK --You havent started tightening up the coupling yet and shifting the tank circuit RF circ current to the dummy load resistance. Each time you open the plates of the Load cap a little more you are decreasing the capacitance and increasing the capacitive reactance XC. This allows more current to flow in the dummy load resistor or the antenna.

When you get to full load you will have opened the Plate Load capactor to the point that the XC is approx equal to the dummy load or antenna resistance. At this point you will have used half of the stored energy in the tank and there will be equal RF current flowing thru the Plate load capacitor and the dummy load resistor. At that point with 100 watts output power there will be approx 1.4 RF amps flowing thru the Plate load cap and 1.4 RF amps flowing thru the 50 ohm dummy load.

This is all simple ohms law for parallel resistors, but not too many folks really understand what they are doing or how it works or have just never given it any serious thought.

After you make that initial plate current dip in Tune mode you do not need to do any more dip and load procedure. Only reason you do this initial dip is to get the tank circuit adjusted close to resonance so when you go to CW mode and apply full screen grid voltage to

the finals you dont peg the IP meter if the tank is tuned off resonance. This could damage your finals if left keyed too long at this high Ip level.

Read the very last note in the TS-830 loading procedure. It tells you after they have taught you dip and load you dont have to use it as it isnt best or easiest way to load a Class AB1 linear amp!

It directs you to place meter in RF position and Flip to Send and alternately adjust the plate Load and Tune controls for maximum indicated relative power (RF voltage).

With your wattmeter in line leave your TS830 meter in IP. Now after making that initial plate current dip in Tune mode flip to Send in CW mode and alternately adjust Plate Load and Plate tune controls for approx 100watts output.

Your wattmeter will be far more sensitive to any changes you make than your IP meter. You will quickly be able to find the combination that gives you max rf output power. Take a quick look at IP and it should be close to 225ma. If a little over dont worry about it as 265ma is the real limit.

Lastly, if you are having to increase the Car level at the late stage of tuning you are not setting it high enough in the early Drive control peaking step. There is no reason to have to do this. When you peak the Drive give yourself something to look at. If you peg the ALC meter just reduce the Car level pot to get it off the peg.

Haven't done anything with the TS-520, but my Ts-820 suffered from too much heat in the finals. I replaced the rather tinny Kenwood fan with a medium size 12 volt computer fan.
It gives 3x the airflow and runs of the Kenwood internal supply rail.
Fits on the back of the rig and only sticks out about 25mm.
PS. I also drilled quite a few more ventilation holes and modified the case to allow more airflow above the output tubes. That also helped.

First of all you should not be loading to 240 ma to 250 ma Ip on a TS-520. Check your manual and you will see 200ma is max plate current for 160 watts dc input power.

If resting plate current is changing on you after you have set it several things come to mind:(should be able to set it one time and not worry about it for many hours of operation)

1. Dirty bias voltage adjust pot
2. Screen grid voltage is varying under key down
3. Final tube emission is falling off
4. Anode voltage is falling off

I would place voltmeter on 6146 control grids Pin 5 and watch the dc operating bias voltage under key down. It should be approx -55vdc and stable. If it is drifting shut rig down and unplug it and Deoxit the bias voltage adjust pot and run it thru its range several times and blow out with canned air. Then reset 60ma resting plate current and monitor voltage to see if it is holding at -55vdc. Not often that the -C supply itself has a problem.

If this does not fix problem than would monitor Screen Grid voltage on Pin 3 to make sure it is not varying under key down.

Your output power levels are not too bad. I would do a good coil pack alignment before doing anything else. You can just try peaking the 20 meter Drive and Mixer coils, but is better to do all in the proper sequence.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Hey Terry and everyone:

Sorry this took me so long, I was waiting on parts for my antenna and my AT-230 to arrive in the mail.

I tuned my TS-520 into a dummy load, using the AT-230 as a wattmeter and SWR meter. This is what I observed.

80 meters: Load just about fully meshed, CAR value: 5, 210 ma, 100 watts
40 meters: Load fully meshed, CAR value: 2.75, 210 ma, 80 watts
20 meters: Load 3/4 to meshed, CAR value: 5, 220 ma, 60 watts
15 meters: CAR value: 2.75, 210 ma, 80 watts
10 meters: Load 1/2, CAR value: 4, 210 ma, 80 watts.

I tuned into the center of the band, for voice, on each band.

I noticed that in general, when I keyed the 520 up, the needle for ma would sit at about 240 or 250 ma and then slowly drop off to 210ma on average. I also noticed I had to readjust the bias control for 60ma when I began this whole thing. It was correct the other

day, but changed for some reason.

I got all of the stray RF in my shack under control and I checked my antenna and got it to about 5:1 SWR with a nice torroid on it to choke the stray RF. I got a 59 signal report from SW Washington (I am in SW Idaho). I noticed that my tuner won't match the antenna at all on 40 meters or 20 meters, but will match on 15 and 10. I don't know if that is because of an issue with the radio, or the tuner itself, but it was an observation. I get a better SWR on 40 when I am using my antenna without the tuner. In fact, the ham in Washington couldn't hear me at all when I was passing through the tuner, but gave me the 59 without the tuner.

I opened the radio and visually inspected the components you, Terry, suggested. Nothing looks burned, the coils are still shiny and bright and none of the caps looked like they popped, everything, visually, looks clean.

What should I do now?

OK sorry for the confusion. I am clearly confused on who I am taking to at this point and what the problem is. I dont think we discussed yet how to measure/test the fixed padder caps in any rig. I think we last left off with asking you to load test your rig on each band and not just 40 and 20 meters and reporting back the results?

Terry K9TW

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

I was referring to checking and replacing the padder caps and the other items you described the other day. Brain was helping me tune my TS-520 and the discussion was about complications with that. You mentioned in a couple of previous posts that you were talking about a TS-830. I was concerned there was some confusion about what model of Kenwood was experiencing the issues described in this thread. If they all work the same, I'll get those padder caps tested and look at the other items referred to in your previous post.

I hope that's not more confusing, hehe. Brian knows better than I do and was able to explain the problems better than I could.

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

I am exactly sure what you are asking. If you are asking about how to load a TS520 that has no Tune Ip indication to get that initial plate current dip and is it different than a TS-830 then answer is no difference other than limiting the plate current to 200ma.

Some people with lots of experience load in CW mode. Some do this as they have a good understanding of what is going on and the pre-cautions using this method.

Others do it because the Tune position of their rig quit years ago and too lazy to fix it or dont know how to fix it.

I typically do not teach new folks to load in CW.

However if your rigs Tune position is out and you cannot get that initial plate current dip then you can do it by reducing the Car Level pot to minimum and with meter in Ip position Flip to Send and slowly bring the Car Level up to something under 100ma. Have to be careful because Ip can jump very high pretty quickly with very little more opening of the pot.

When you get say around 80ma to 100ma then adjust the plate Tune capacitor for a dip or minimum in plate current and then unkey the rig. Now ready to use the RF relative power position of the panel meter or your external wattmeter to start coupling load. Flip to Send and alternately adjust Plate Load and Plate Tune controls for max relative power on your RF meter position or approx 100 watts output on your wattmeter. Unkey the rig.

Watching the Ip meter flip to send again and if you are reasonably close to 200ma Ip you are done and ready to operate CW or SSB.

WIth a good Tune position I recommend you follow the instructions in your TS520 manual. Only confusing step is peaking the Drive which says to adjust for maximum meter deflection and everyone and I mean everyone asks "what maximum"? The ALC black box maximum or the meter full scale maximum. As I think I told you black box is meaningless at this step but OK to just peak Drive control at max range on it.

After you get that initial plate current dip in Tune mode then all the Kenwood instruction manuals direct you to load by alternately adjusting :Load and Tune controls for max RF relative power. If you have an external wattmeter leave meter in Ip and load for approx 100 watts out without exceeding 200ma.

Subject: RE: Re: [TS-520_820_530_830] New Ham, Tuning issues

Brian:

No problem with using a Key to load the rig. Just not necessary when bench testing a rig. The 830 manual contributes to this when early on they tell you to connect dummy load or antenna and connect a Key and then flip to Send and check resting plate current. However they fail to tell you to press the Key or close the slider if a straight Key. Later under Transmission section under CW header they tell you again to install a Key. Poorly written.

When you turn the Plate Load cap control CW off the full CCW position and you see the RF output power on the wattmeter go down do you then immediately adjust the Plate Tune capacitor to try to bring the RF output power back up?

Anytime the Load cap is moved open or closed you need to make a slight adjustment with the Tune capacitor to restore the tank to resonance. What happens when you do this?

Typically once the reactance of the Plate Load capacitor is close to the impedance of the load (antenna or dummy load) opening the plates (CW) any more usually does not result in anymore RF output on the wattmeter. You reach a point where opening the plates more does not result in coupling any more load. The final tubes just cannot supply any more RF Line current to the Tank.

There is no doubt that loading on 40 meters into a 50 ohm dummy load you should not be at maximum RF output with the Plate Load cap full CCW (plates fully meshed). As you suggest it is not "normal". You know that from your own TS-830.

As I mentioned this is indicative of bad fixed padder caps that are switched in on the lower bands. The reason that this is necessary is if they installed an air variable capacitor that had the necessary high level of capacitance on the lower bands it would then have a minimum capacitance with the plates completely open that would be far too high to function on higher bands. 10 meters is the biggest challenge for the designers. It directs you to place meter in RF position and Flip to Send and alternately adjust the plate Load and Tune controls for maximum indicated relative power (RF voltage).

With your wattmeter in line leave your TS830 meter in IP. Now after making that initial plate current dip in Tune mode flip to Send in CW mode and alternately adjust Plate Load and Plate tune controls for approx 100watts output.

Your wattmeter will be far more sensitive to any changes you make than your IP meter. You will quickly be able to find the combination that gives you max rf output power. Take a quick look at IP and it should be close to 225ma. If a little over dont worry about it as 265ma is the real limit.

Lastly, if you are having to increase the Car level at the late stage of tuning you are not setting it high enough in the early Drive control peaking step. There is no reason to have to do this. When you peak the Drive give yourself something to look at. If you peg the ALC meter just reduce the Car level pot to get it off the peg.

Sounds like an antenna issue caused the radio problems.

Subject: [TS-520_820_530_830] RE: New Ham, Tuning issues

Hey Terry and everyone:

Sorry this took me so long, I was waiting on parts for my antenna and my AT-230 to arrive in the mail.

I tuned my TS-520 into a dummy load, using the AT-230 as a wattmeter and SWR meter. This is what I observed.

80 meters: Load just about fully meshed, CAR value: 5, 210 ma, 100 watts
40 meters: Load fully meshed, CAR value: 2.75, 210 ma, 80 watts
20 meters: Load 3/4 to meshed, CAR value: 5, 220 ma, 60 watts
15 meters: CAR value: 2.75, 210 ma, 80 watts
10 meters: Load 1/2, CAR value: 4, 210 ma, 80 watts.

I tuned into the center of the band, for voice, on each band.

I noticed that in general, when I keyed the 520 up, the needle for ma would sit at about 240 or 250 ma and then slowly drop off to 210ma on average. I also noticed I had to readjust the bias control for 60ma when I began this whole thing. It was correct the other day, but changed for some reason.

I got all of the stray RF in my shack under control and I checked my antenna and got it to about 5:1 SWR with a nice torroid on it to choke the stray RF. I got a 59 signal report from SW Washington (I am in SW Idaho). I noticed that my tuner won't match the antenna at all on 40 meters or 20 meters, but will match on 15 and 10. I don't know if that is because of an issue with the radio, or the tuner itself, but it was an observation. I get a better SWR on 40 when I am using my antenna without the tuner. In fact, the ham in Washington couldn't hear me at all when I was passing through the tuner, but gave me the 59 without the tuner.

I opened the radio and visually inspected the components you, Terry, suggested. Nothing looks burned, the coils are still shiny and bright and none of the caps looked like they popped, everything, visually, looks clean.

What should I do now?

with a key plugged in you don't get any output with the alternate procedure without closing
the key for obvious reasons. I've been so used to how the radio responded when I switched
over from tune to CW with a key connected that I ended up thinking the key was necessary.
 My bad. For me the long procedure from the manual works fine since I always have the key
connected and normally have the radio in VOX mode (to save wear on the send switch) but I
have a better understanding now. Thank you. I will also study the diagram to try to
better understand the relationship between the load capacitor and antenna load.
>>>>>>>
>>>>>>>
>>>>>>>This will also help Jason since I took him through the long procedure from the
manual that uses a key. He can just unplug his keyer and will be able to move from tuning
to loading once he has the drive and plate a resonance (peaked and dipped) without all of
the additional gyrations.
>>>>>>>
>>>>>>>
>>>>>>>Questions: This still leaves Jason's TS-520's issue with load. Even though I was
using the long procedure with the key, I think the results are still accurate. He is
getting a maximum output of 70w at 200ma with the load at min (fully CCW) and reducing the
load capacitance (increasing the load/turning load CW) actually reduces his output. This
isn't normal, right? I can simulate this on my TS-830 but it pains me. If I intentionally
turn the load up too much, output falls off as I increase the load. So...I think in
Jason's TS520 it is as if even at maximum capacitance (minimum load) he doesn't have enough
to balance against the 50 ohm dummy load---resonance is off the minimum end of the load.
 Does that sound like a reasonable conclusion? Is the next step for us to try the tune up
procedure on all bands and report back (your 10m suggestion from before) or is there
something else that we should check first?

Topic: 44440 Message: 44982

Installing an 'ugly balun' and getting rid of that stray RF really helped, but it still seems there is something mechanically wrong with the 520. I think that not being able to tune it properly is hurting my AT-230's ability to successfully tune my antenna. I noticed that on 10 and 15 the tuner works fine, but when I get to 20 or 40 it won't match at all. I also still need to ground the radio itself, I have the rig plugged into a standard wall outlet, but in my house, the wall outlets are not grounded (older home), maybe it'll help a little to get the rig properly grounded.

I wish I had the cash to have a professional look at it and realign everything for me. Either way, I'll work on testing those issues that were mentioned by Terry and see where that takes me.

I am exactly sure what you are asking. If you are asking about how to load a TS520 that has no Tune Ip indication to get that initial plate current dip and is it different than a TS-830 then answer is no difference other than limiting the plate current to 200ma.

Some people with lots of experience load in CW mode. Some do this as they have a good understanding of what is going on and the pre-cautions using this method.

Others do it because the Tune position of their rig quit years ago and too lazy to fix it or dont know how to fix it.

I typically do not teach new folks to load in CW.

However if your rigs Tune position is out and you cannot get that initial plate current dip then you can do it by reducing the Car Level pot to minimum and with meter in Ip position

Flip to Send and slowly bring the Car Level up to something under 100ma. Have to be careful because Ip can jump very high pretty quickly with very little more opening of the pot.

When you get say around 80ma to 100ma then adjust the plate Tune capacitor for a dip or minimum in plate current and then unkey the rig. Now ready to use the RF relative power position of the panel meter or your external wattmeter to start coupling load. Flip to Send and alternately adjust Plate Load and Plate Tune controls for max relative power on your RF meter position or approx 100 watts output on your wattmeter. Unkey the rig.

Watching the Ip meter flip to send again and if you are reasonably close to 200ma Ip you are done and ready to operate CW or SSB.

WIth a good Tune position I recommend you follow the instructions in your TS520 manual. Only confusing step is peaking the Drive which says to adjust for maximum meter deflection and everyone and I mean everyone asks "what maximum"? The ALC black box maximum or the meter full scale maximum. As I think I told you black box is meaningless at this step but OK to just peak Drive control at max range on it.

After you get that initial plate current dip in Tune mode then all the Kenwood instruction manuals direct you to load by alternately adjusting :Load and Tune controls for max RF relative power. If you have an external wattmeter leave meter in Ip and load for approx 100 watts out without exceeding 200ma.

Subject: RE: Re: [TS-520_820_530_830] New Ham, Tuning issues

Brian:

No problem with using a Key to load the rig. Just not necessary when bench testing a rig. The 830 manual contributes to this when early on they tell you to connect dummy load or antenna and connect a Key and then flip to Send and check resting plate current. However they fail to tell you to press the Key or close the slider if a straight Key. Later under Transmission section under CW header they tell you again to install a Key. Poorly written.

When you turn the Plate Load cap control CW off the full CCW position and you see the RF output power on the wattmeter go down do you then immediately adjust the Plate Tune capacitor to try to bring the RF output power back up?

Anytime the Load cap is moved open or closed you need to make a slight adjustment with the Tune capacitor to restore the tank to resonance. What happens when you do this?

Typically once the reactance of the Plate Load capacitor is close to the impedance of the load (antenna or dummy load) opening the plates (CW) any more usually does not result in anymore RF output on the wattmeter. You reach a point where opening the plates more does not result in coupling any more load. The final tubes just cannot supply any more RF Line current to the Tank.

There is no doubt that loading on 40 meters into a 50 ohm dummy load you should not be at maximum RF output with the Plate Load cap full CCW (plates fully meshed). As you suggest it is not "normal". You know that from your own TS-830.

As I mentioned this is indicative of bad fixed padder caps that are switched in on the lower bands. The reason that this is necessary is if they installed an air variable capacitor that had the necessary high level of capacitance on the lower bands it would then have a minimum capacitance with the plates completely open that would be far too high to function on higher bands. 10 meters is the biggest challenge for the designers. Same for the Plate Tune capacitor.

If you get time it would be good to see if it loads normal on 15 and 10 meters. I would try loading on all the bands and make a chart of how it behaves. Where does the plate Load cap end up for approx 100 watts output at 200ma Ip.

One other thing you should look at if comfortable is the main RF plate choke and the small VHF choke at a right angle at its base and the rf bypass cap at its base. If these show signs of overheating then will need to be replaced. The by pass cap can actually physically split the case open.

Need to have rig unplugged and let set for awhile to led bleeders discharge the HV filter caps. Then remove PA cage cover. Then connect ground jumper from top of plate choke and ground for a few seconds. Now safe to use a good flashlite and inspect these items.

I would also look at both capacitor shaft couplers at the PA cage and make sure screws are tight. Can also watch the travel and make sure full open and full close align with markings

on the front panel.

Hi Terry:

Ah ha. I am a CW op so I always have had a key plugged in (but no mic). Anyway, with a key plugged in you don't get any output with the alternate procedure without closing the key for obvious reasons. I've been so used to how the radio responded when I switched over from tune to CW with a key connected that I ended up thinking the key was necessary. My bad. For me the long procedure from the manual works fine since I always have the key connected and normally have the radio in VOX mode (to save wear on the send switch) but I have a better understanding now. Thank you. I will also study the diagram to try to better understand the relationship between the load capacitor and antenna load.

This will also help Jason since I took him through the long procedure from the manual that uses a key. He can just unplug his keyer and will be able to move from tuning to loading once he has the drive and plate a resonance (peaked and dipped) without all of the additional gyrations.

Questions: This still leaves Jason's TS-520's issue with load. Even though I was using the long procedure with the key, I think the results are still accurate. He is getting a maximum output of 70w at 200ma with the load at min (fully CCW) and reducing the load capacitance (increasing the load/turning load CW) actually reduces his output. This isn't normal, right? I can simulate this on my TS-830 but it pains me. If I intentionally turn the load up too much, output falls off as I increase the load. So...I think in Jason's TS520 it is as if even at maximum capacitance (minimum load) he doesn't have enough to balance against the 50 ohm dummy load---resonance is off the minimum end of the load. Does that sound like a reasonable conclusion? Is the next step for us to try the tune up procedure on all bands and report back (your 10m suggestion from before) or is there something else that we should check first?

Thanks,
Brian (and Jason)

Subject: RE: Re: Re: [TS-520_820_530_830] RE: New Ham, Tuning issues

You dont need the key or vox or any of the gyrations you are putting your self thru to load your TS830.

The reason Ip indicates approx 60ma when you switch from Tune to CW mode is that you have the plates meshed on the Plate load cap and you are shunting the RF current around the dummy load and circulating it in the Tank.

It is OK to crack the Plate Load control open a little at initial loading so you can see 70 or 80 ma or so if that helps you.

At this point with plates fully meshed you have maximum capacitance and lowest capacitive reactance so the RF current in the tank is going to like to flow thru the plate load cap

and not thru the dummy load. Sometime look at formula for Xc and you will see it is an inverse relationship. It will help you understand what I am telling you.

OK --You havent started tightening up the coupling yet and shifting the tank circuit RF circ current to the dummy load resistance. Each time you open the plates of the Load cap a little more you are decreasing the capacitance and increasing the capacitive reactance XC. This allows more current to flow in the dummy load resistor or the antenna.

When you get to full load you will have opened the Plate Load capactor to the point that the XC is approx equal to the dummy load or antenna resistance. At this point you will have used half of the stored energy in the tank and there will be equal RF current flowing thru the Plate load capacitor and the dummy load resistor. At that point with 100 watts output power there will be approx 1.4 RF amps flowing thru the Plate load cap and 1.4 RF amps flowing thru the 50 ohm dummy load.

This is all simple ohms law for parallel resistors, but not too many folks really understand what they are doing or how it works or have just never given it any serious thought.

After you make that initial plate current dip in Tune mode you do not need to do any more dip and load procedure. Only reason you do this initial dip is to get the tank circuit adjusted close to resonance so when you go to CW mode and apply full screen grid voltage to the finals you dont peg the IP meter if the tank is tuned off resonance. This could damage your finals if left keyed too long at this high Ip level.

Read the very last note in the TS-830 loading procedure. It tells you after they have taught you dip and load you dont have to use it as it isnt best or easiest way to load a Class AB1 linear amp!

It directs you to place meter in RF position and Flip to Send and alternately adjust the plate Load and Tune controls for maximum indicated relative power (RF voltage).

With your wattmeter in line leave your TS830 meter in IP. Now after making that initial plate current dip in Tune mode flip to Send in CW mode and alternately adjust Plate Load and Plate tune controls for approx 100watts output.

Your wattmeter will be far more sensitive to any changes you make than your IP meter. You will quickly be able to find the combination that gives you max rf output power. Take a quick look at IP and it should be close to 225ma. If a little over dont worry about it as 265ma is the real limit.

Lastly, if you are having to increase the Car level at the late stage of tuning you are not setting it high enough in the early Drive control peaking step. There is no reason to have to do this. When you peak the Drive give yourself something to look at. If you peg the ALC meter just reduce the Car level pot to get it off the peg.

Topic: 44440 Message: 44983

Your very first goal is to be able to load the rig into a dummy load on all bands. Worry about using a tuner to load into a multi-band antenna after you are certain you can load "normally" in to the dummy load.

If you can load the rig successfully into dummy load with the tuner in the Bypass Mode (just using the tuner for the wattmeter/SWR meter function) then nothing is wrong with your Pi-Network in the rig unless you are at extreme ends of the Plate Load cap or the Plate Tune cap position doesnt align relatively close to the white panel marking for the band you are loading on.

If you end up having the Plate Load or Plate tune caps at odd positions to attain your 80 to 100 watts into the dummy load you may have bad fixed padder caps.

What would be "normal" is approx 90 to 100 watts into 50 ohm dummy load on all bands with exception of 10 meters (80 watts) at approx 200ma plate current and you should see very close to 1:1 SWR into your dummy load.

If you can do this then time to discuss the antenna and the tuner issues.

Again, your first effort should be to make sure the rig can load normally into a dummy load. This proves your dummy load is good, your interconnecting coax jumpers are good, and the rig is good.

If you cannot do this then no reason to attempt to use the tuner to load in to a multi-band antenna of any type.

The tuner is taking the impedance that the antenna presents at the end of whatever kind of feed line you are using and converting it to an impedance that your rigs Pi-network can match. A multiband antenna can present a wide range of impedances (combination of resistance and reactive) to your rig. The rig cannot match very high impedances (thousands of ohms) that a multiband antenna can present. If you have very high impedance at the end of the feed line in the shack then RF can be a problem in the shack. End fed can present several thousand ohms which means very high RF voltage at the input to the tuner. Sometimes need to install counter poise to resolve this situation.

Describe again what the antenna configuration is. Is this a OCF dipole or a 135 foot flat top fed with 300 ohm ladder line or open wire feeders or a random length end fed ??

It could be that the Tuner has an issue?

So tell us first if you can load rig normally into the dummy load? If so, then describe the complete antenna configuration.

Having resting plate current changing has nothing to do with your antenna or your tuner. You can unscrew your coax connector off back of rig and set resting plate current. Fix that first.

Subject: [TS-520_820_530_830] RE: New Ham, Tuning issues

Hey Terry and everyone:

Sorry this took me so long, I was waiting on parts for my antenna and my AT-230 to arrive in the mail.

I tuned my TS-520 into a dummy load, using the AT-230 as a wattmeter and SWR meter. This is what I observed.

80 meters: Load just about fully meshed, CAR value: 5, 210 ma, 100 watts
40 meters: Load fully meshed, CAR value: 2.75, 210 ma, 80 watts
20 meters: Load 3/4 to meshed, CAR value: 5, 220 ma, 60 watts
15 meters: CAR value: 2.75, 210 ma, 80 watts
10 meters: Load 1/2, CAR value: 4, 210 ma, 80 watts.

I tuned into the center of the band, for voice, on each band.

I noticed that in general, when I keyed the 520 up, the needle for ma would sit at about 240 or 250 ma and then slowly drop off to 210ma on average. I also noticed I had to readjust the bias control for 60ma when I began this whole thing. It was correct the other day, but changed for some reason.

I got all of the stray RF in my shack under control and I checked my antenna and got it to about 5:1 SWR with a nice torroid on it to choke the stray RF. I got a 59 signal report from SW Washington (I am in SW Idaho). I noticed that my tuner won't match the antenna at all on 40 meters or 20 meters, but will match on 15 and 10. I don't know if that is because of an issue with the radio, or the tuner itself, but it was an observation. I get a better SWR on 40 when I am using my antenna without the tuner. In fact, the ham in Washington

couldn't hear me at all when I was passing through the tuner, but gave me the 59 without the tuner.

I opened the radio and visually inspected the components you, Terry, suggested. Nothing looks burned, the coils are still shiny and bright and none of the caps looked like they popped, everything, visually, looks clean.

What should I do now?

I was referring to checking and replacing the padder caps and the other items you described the other day. Brain was helping me tune my TS-520 and the discussion was about complications with that. You mentioned in a couple of previous posts that you were talking about a TS-830. I was concerned there was some confusion about what model of Kenwood was experiencing the issues described in this thread. If they all work the same, I'll get those padder caps tested and look at the other items referred to in your previous post.

I hope that's not more confusing, hehe. Brian knows better than I do and was able to explain the problems better than I could.

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

I am exactly sure what you are asking. If you are asking about how to load a TS520 that has no Tune Ip indication to get that initial plate current dip and is it different than a TS-830 then answer is no difference other than limiting the plate current to 200ma.

Some people with lots of experience load in CW mode. Some do this as they have a good understanding of what is going on and the pre-cautions using this method.

Others do it because the Tune position of their rig quit years ago and too lazy to fix it or dont know how to fix it.

I typically do not teach new folks to load in CW.

However if your rigs Tune position is out and you cannot get that initial plate current dip then you can do it by reducing the Car Level pot to minimum and with meter in Ip position Flip to Send and slowly bring the Car Level up to something under 100ma. Have to be careful because Ip can jump very high pretty quickly with very little more opening of the pot.

When you get say around 80ma to 100ma then adjust the plate Tune capacitor for a dip or minimum in plate current and then unkey the rig. Now ready to use the RF relative power position of the panel meter or your external wattmeter to start coupling load. Flip to Send and alternately adjust Plate Load and Plate Tune controls for max relative power on your RF meter position or approx 100 watts output on your wattmeter. Unkey the rig.

Watching the Ip meter flip to send again and if you are reasonably close to 200ma Ip you are done and ready to operate CW or SSB.

WIth a good Tune position I recommend you follow the instructions in your TS520 manual. Only confusing step is peaking the Drive which says to adjust for maximum meter deflection and everyone and I mean everyone asks "what maximum"? The ALC black box maximum or the meter full scale maximum. As I think I told you black box is meaningless at this step but OK to just peak Drive control at max range on it.

After you get that initial plate current dip in Tune mode then all the Kenwood instruction manuals direct you to load by alternately adjusting :Load and Tune controls for max RF relative power. If you have an external wattmeter leave meter in Ip and load for approx 100 watts out without exceeding 200ma.

Subject: RE: Re: [TS-520_820_530_830] New Ham, Tuning issues

Brian:

No problem with using a Key to load the rig. Just not necessary when bench testing a rig. The 830 manual contributes to this when early on they tell you to connect dummy load or antenna and connect a Key and then flip to Send and check resting plate current. However they fail to tell you to press the Key or close the slider if a straight Key. Later under Transmission section under CW header they tell you again to install a Key. Poorly written.

When you turn the Plate Load cap control CW off the full CCW position and you see the RF output power on the wattmeter go down do you then immediately adjust the Plate Tune capacitor to try to bring the RF output power back up?

Anytime the Load cap is moved open or closed you need to make a slight adjustment with the Tune capacitor to restore the tank to resonance. What happens when you do this?

Typically once the reactance of the Plate Load capacitor is close to the impedance of the load (antenna or dummy load) opening the plates (CW) any more usually does not result in anymore RF output on the wattmeter. You reach a point where opening the plates more does not result in coupling any more load. The final tubes just cannot supply any more RF Line current to the Tank.

There is no doubt that loading on 40 meters into a 50 ohm dummy load you should not be at maximum RF output with the Plate Load cap full CCW (plates fully meshed). As you suggest it is not "normal". You know that from your own TS-830.

There is nothing you can do to prevent a carbon track from forming on your final PC board other than visual inspection. I have never seen a carbon track develop in normal operation.

With the TS520 with phenolic octal sockets, terminal strips, and point to point wiring it would be rare for a track to develop across the phenolic socket material. There would be three possible paths. From SG pin to chassis ground, to cathode pin, and to heater pin. Two sources of voltage. Normal approx 250vdc SG supply and 900vdc with tube arc over.

With a TS-520S you have a final PC board which replaced the older style point to point wiring. The pc board has the octal sockets soldered to the board. Very unlikely for carbon track to develop between the solder pads of the tube pins. You can perform visual and make sure no residual flux and no tracking is occurring.

What I have seen on more than one occasion is the PC board area directly under the 100 ohm Grid Stopper resistors and the 470ua chokes deeply burned black. The PC traces are typically lifted or gone as well. This occurs when there is a hard fault that occurs and heavy current flows thru the choke coil and the resistors back to the SG supply on the HV rectifier board. Usually when this occur R6 470 ohm resistor is also burned and the board under it may be blackened and charred and/or the PC foils lifted or gone. The half wave diode may be gone as well.

What would cause this is a tube arc over and not likely a fault from SG element in the tube contacting another element in the tube. You have two sources of voltage to produce heavy current in the SG feed. Normal 250vdc supply and 900vdc in event of arc over.

Ask yourself what would limit the current if either source was pushing that current.

R6 470 ohm resistor on the HV rectifier board is the highest resistance. 250/470 = .5 amps and 900/470 = 2 amps. Either current would would hurt 470ua choke, grid stopper resistors, and R6 470 ohm resistor. The heat produced over time is what chars the board under these components and ultimately lifts the foil traces. It is not an instant failure. It takes time to develop and propagate until failure occurs. Carbon resistors can take a lot of overcurrent for a long time, but horizontally oriented they can "cook" the board in close proximity below them.

I am pretty sure I provided you with protection mod for your finals. It included MOVs at the SG of the final tubes to clamp the voltage to no more than approx 300vdc. The MOV is for 900vdc anode arc over protection and will not protect against fault current from the normal SG supply somehow going to ground inside the tube or at the tube socket pins on the PC board.

I forgot to mention. We are all working with 35 to 40 year old radios. The boards in these rigs are not the nice glass boards with heavy plating that we have today. These are old style phenolic boards. Very easy to lift a trace/pad and many have had repeated un-soder and re-solder evolutions on them.

I have a couple of complete sets of spare boards for my TS830s and partial sets for my TS820 and TS520.

I recommend you consider this and/or buying a tech special or parts rig. Tech specials are not cheap on Ebay. There is a limited supply of these rigs so may want to consider spending the money. Today almost impossible to find a RF board under $100. .

I agree not practical to use an Xacto knife or Dremel tool to attempt to remove carbon tracks on boards. When these deep tracks occur the board is pretty much junk.

I dont know why Mr. Davidson opted not to repair his radio. When you have this kind of failure relatively easy to contact Bob Mansker and buy a replacement final board and HV rect board. This forum is here to help with these kinds of repairs. We all have different decision making processes and chose how we spend our disposable income.

I have tried to position myself to keep my treasures on the air for a long time, but kind of like a old car can come a point where no longer willing to put anymore money in it.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

There is nothing you can do to prevent a carbon track from forming on your final PC board other than visual inspection. I have never seen a carbon track develop in normal operation.

With the TS520 with phenolic octal sockets, terminal strips, and point to point wiring it would be rare for a track to develop across the phenolic socket material. There would be three possible paths. From SG pin to chassis ground, to cathode pin, and to heater pin. Two sources of voltage. Normal approx 250vdc SG supply and 900vdc with tube arc over.

With a TS-520S you have a final PC board which replaced the older style point to point wiring. The pc board has the octal sockets soldered to the board. Very unlikely for carbon track to develop between the solder pads of the tube pins. You can perform visual and make sure no residual flux and no tracking is occurring.

What I have seen on more than one occasion is the PC board area directly under the 100 ohm Grid Stopper resistors and the 470ua chokes deeply burned black. The PC traces are typically lifted or gone as well. This occurs when there is a hard fault that occurs and heavy current flows thru the choke coil and the resistors back to the SG supply on the HV rectifier board. Usually when this occur R6 470 ohm resistor is also burned and the board under it may be blackened and charred and/or the PC foils lifted or gone. The half wave diode may be gone as well.

What would cause this is a tube arc over and not likely a fault from SG element in the tube contacting another element in the tube. You have two sources of voltage to produce heavy current in the SG feed. Normal 250vdc supply and 900vdc in event of arc over.

Ask yourself what would limit the current if either source was pushing that current.

R6 470 ohm resistor on the HV rectifier board is the highest resistance. 250/470 = .5 amps and 900/470 = 2 amps. Either current would would hurt 470ua choke, grid stopper resistors, and R6 470 ohm resistor. The heat produced over time is what chars the board under these components and ultimately lifts the foil traces. It is not an instant failure. It takes time to develop and propagate until failure occurs. Carbon resistors can take a lot of overcurrent for a long time, but horizontally oriented they can "cook" the board in close proximity below them.

I am pretty sure I provided you with protection mod for your finals. It included MOVs at the SG of the final tubes to clamp the voltage to no more than approx 300vdc. The MOV is for 900vdc anode arc over protection and will not protect against fault current from the normal SG supply somehow going to ground inside the tube or at the tube socket pins on the PC board.

The fan in any of the KW hybrids is not designed to provide a high volume of air into the final amplifier. The fan is designed to move air. Final amplifier heat radiates into the surrounding area in the final cage and the fan simply pulls air into the final enclosure and push heated air out of the vents. There is no added benefit by replacing the factory KW hybrid fan with a fan that produces a higher volume of air flow. The important thing is to keep the air flow moving, the fan blades, and fan shroud clean of dust. In addition, keep the final tube's clean of dust collection. Dust collected on the final tubes acts as a "blanket", trapping heated air against the final tubes. Dust collection on the fan blades and fan shroud reduces the effectiveness of the fan.

Keep the vents on the side and top of the KW hybrid open, do not stack equipment on top or along the sides of the KW hybrid. I've seen a lot of ham shack pictures showing KW hybrid transceivers with ham gear stacked on top and close along the sides. I often wonder how long that transceiver will continue to operate before the final tubes overheat? While this may appear to "look neat", it's NOT! If this is how your ham shack is then it won't be long before the KW hybrid final tubes overheat and fail and it will not be caused by failure of the final tubes but because if the equipment "blocking" the vent holes resulting in significant reduction in air flow.

Ask yourself, would you allow air flow through your cars radiator to be blocked? If so how long would it take before your car's motor overheats? The same applies to your KW hybrid so don't be foolish by stacking gear on top and close along the sides of your KW hybrid. Also, don't build a shelving unit then place your KW hybrid in the shelf space that blocks air flow, your KW hybrid won't like that.

One more thing I forgot to mention.

The final amplifier, including the final tubes and associated components, and the power supplies are not designed to operate at 100% duty cycle! RTTY and PSK are 100% duty cycle modes. If you operate at full power even with short transmit durations, you are putting excess stress on the final amplifier tubes, amplifier components, and the power supplies. This is especially true when operating in a contest even with short transmit durations, where transmissions are quite often one right after the other. So keep the power output less than 50 watts, your KW hybrid will last much longer. As one response said, if you want higher power then use an amp that has the ability to withstand 100% duty cycle modes.

Topic: 44440 Message: 44990

Okay, I'm confused.

My TS-830S -- when compared with my super clean sounding TS-530S -- exhibits a slight amount of receiver distortion on strong signals. The 830's frequency response is also not quite as open and transparent as the 530's, though the 830's noise floor sounds lower. Both radios' audio outputs are connected to my SP-230, so speaker response is identical.

Would swapping the 830's 1N60 diodes with Schottky diodes make a positive difference? I have read scores of forum queries on this topic and the answers appear to be almost equally divided between "Wow! What a difference!" and "Don't bother. If it ain't broke...."

I can certainly live with the 830's received audio and am reluctant to mess with any more fragile circuit board traces if the results will be negligible. However, if I can make my 830 sound as smooth and bright as my 530, I'd take the chance.

So, what's your experience, please?

Thanks (again) and 73,

Craig
W3CRR

I have discovered a output from my PLL board from conn 5 pin 2[VFO In] to a rca phono jack at the rear of the rig,as there is two extra holes for outputs if needed.

What could you use this input for.

On all of the Kenwood hybrids I've owned, the cooling fan functions as an exhaust fan pulling air through the vents and final cage, and exhausting the air from the rear of the fan housing, including the 520S, 820S, and 830S I still own.

I forgot to mention. We are all working with 35 to 40 year old radios. The boards in these rigs are not the nice glass boards with heavy plating that we have today. These are old style phenolic boards. Very easy to lift a trace/pad and many have had repeated un-soder and re-solder evolutions on them.

I have a couple of complete sets of spare boards for my TS830s and partial sets for my TS820 and TS520.

I recommend you consider this and/or buying a tech special or parts rig.! Tech specials are not cheap on Ebay. There is a limited supply of these rigs so may want to consider spending the money. Today almost impossible to find a RF board under $100. .

I agree not practical to use an Xacto knife or Dremel tool to attempt to remove carbon tracks on boards. When these deep tracks occur the board is pretty much junk.

I dont know why Mr. Davidson opted not to repair his radio. When you have this kind of failure relatively easy to contact Bob Mansker and buy a replacement final board and HV rect board. This forum is here to help with these kinds of repairs. We all have different decision making processes and chose how we spend our disposable income.

I have tried to position myself to keep my treasures on the air for a long time, but kind of like a old car can come a point where no longer willing to put anymore money in it.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

There is nothing you can do to prevent a carbon track from forming on your final PC board other than visual inspection. I have never seen a carbon track develop in normal operation.

With the TS520 with phenolic octal sockets, terminal strips, and point to point wiring it would be rare for a track to develop across the phenolic socket material. There would be three possible paths. From SG pin to chassis ground, to cathode pin, and to heater pin. Two sources of voltage. No! rmal approx 250vdc SG supply and 900vdc with tube arc over.

With a TS-520S you have a final PC board which replaced the older style point to point wiring. The pc board has the octal sockets soldered to the board. Very unlikely for carbon track to develop between the solder pads of the tube pins. You can perform visual and make

sure no residual flux and no tracking is occurring.

What I have seen on mo! re than one occasion is the PC board area directly under the 100 ohm Grid Stopper resistors and the 470ua chokes deeply burned black. The PC traces are typically lifted or gone as well. This occurs when there is a hard fault that occurs and heavy current flows thru the choke coil and the resistors back to the SG supply on the HV rectifier board. Usually when this occur R6 470 ohm resistor is also burned and the board under it may be blackened and charred and/or the PC foils lifted or gone. The half wave diode may be gone as well.

What would cause this is a tube arc over and not likely a fault from SG element in the tube contacting another element in! the tube. You have two sources of voltage to produce heavy current in the SG feed. Normal 250vdc supply and 900vdc in event of arc over.

Ask yourself what would limit the current if either source was pushing that current.

R6 470 ohm resistor on the HV rectifier board is the highest resistance. 250/470 = .5 amps and 900/470 = 2 amps. Either current would would hurt 470ua choke, grid stopp! er resistors, and R6 470 ohm resistor. The heat produced over time is what chars the board under these components and ultimately lifts the foil traces. It is not an instant failure. It takes time to develop and propagate until failure occurs. Carbon resistors can take a lot of overcurrent for a long time, but horizontally oriented they can "cook" the board in close proximity below them.

I am pretty sure I provided you with protection mod for your finals. It included MOVs at the SG of the final tubes to clamp the voltage to no more than approx 300vdc. The MOV is for 900vdc anode arc over protection and will not protect against f! ault current from the normal SG supply somehow going to ground inside the tube or at the tube socket pins on the PC board.

If you read the RCA 6146 tube data sheet you will see that max envelope temperature is 260 degrees C and that the tube is designed to run in free air with no additional cooling required.

In the old boatanchor days of Heath Apaches and Johnson Vikings and many similar transmitters no cooling fan was installed by the manufacturer. The later Heath SB and HW series transceivers had no cooling fans.

In those old boatanchors there was a lot of open space around the 6146 finals. In the transceivers to follow a small PA cage was the norm. One of first thing most of us did was to sit a muffin or whisper fan on top the PA cage and pull air from that PA cage. All kinds of tricks to slow them down and rubber mount them to quiet them down. We did this without any evidence that the fans were needed or would increase the life of the finals. No empirical data was compiled. Just seemed like needed a fan and a fan couldnt hurt. I did on my Heath transceivers.

However never gave it a thought to put a cooling fan on the Apache or Viking.

Kenwood gave us a nice slow quiet fan and it is more than adequate to ensure we dont exceed the 6146 tube envelop temperatures and ensure long life if we load and operate the radio properly for each mode we run.

Mike give very good advice. Keep fan cleaned and lubed and as he says do not stack other gear on or around the rig in an enclosed mounting position.

I cannot ever envision a time I would need to increase the cooling capacity of the factory fan. I get rigs on the bench often that have the original S2001A finals and no after market air mover installed.

I forgot to mention that those old transmitters and transceivers were all tube rigs with lots of tubes (20 or more) so they produced much more heat and had no fan.

The KW hybrids only have 3 tubes so total heat load is significantly lower by comparison.

I am not saying dont need a fan on a Hybrid. I am in favor of the KW fan design and if cleaned and lubed will provide years of quiet trouble free service.

I am just saying I dont understand the need for increasing the cooling capacity? What mode are we talking? Is the max envelope temperature being exceeded running this mode? I am a SSB/CW Op so no experience with FSK or PSK modes but common sense would dictate not loading to max IP when running a continuous duty cycle mode. If you look at the KW hybrid design some models have reduced SG voltage for FSK (I will let you figure out how they do that). Too bad the instruction manuals dont give more information on how to load the rigs for these kinds of modes.

5 : 1 SWR ?

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Your very first goal is to be able to load the rig into a dummy load on all bands. Worry about using a tuner to load into a multi-band antenna after you are certain you can load "normally" in to the dummy load.

If you can load the rig successfully into dummy load with the tuner in the Bypass Mode (just using the tuner for the wattmeter/SWR meter function) then nothing is wrong with your Pi-Network in the rig unless you are at extreme ends of the Plate Load cap or the Plate Tune cap position doesnt align relatively close to the white panel marking for the band you are loading on.

If you end up having the Plate Load or Plate tune caps at odd positions to attain your 80 to 100 watts into the dummy load you may have bad fixed padder caps.

What would be "normal" is approx 90 to 100 watts into 50 ohm dummy load on all bands with exception of 10 meters (80 watts) at approx 200ma plate current and you should see very close to 1:1 SWR into your dummy load.

If you can do this then time to discuss the antenna and the tuner issues.

Again, your first effort should be to make sure the rig can load normally into a dummy load. This proves your dummy load is good, your interconnecting coax jumpers are good, and the rig is good.

If you cannot do this then no reason to attempt to use the tuner to load in to a multi-band antenna of any type.

The tuner is taking the impedance that the antenna presents at the end of whatever kind of feed line you are using and converting it to an impedance that your rigs Pi-network can match. A multiband antenna can present a wide range of impedances (combination of resistance and reactive) to your rig. The rig cannot match very high impedances (thousands of ohms) that a multiband antenna can present. If you have very high impedance at the end of the feed line in the shack then RF can be a problem in the shack. End fed can present several thousand ohms which means very high RF voltage at the input to the tuner. Sometimes need to install counter poise to resolve this situation.

Describe again what the antenna configuration is. Is this a OCF dipole or a 135 foot flat top fed with 300 ohm ladder line or open wire feeders or a random length end fed ??

It could be that the Tuner has an issue?

So tell us first if you can load rig normally into the dummy load? If so, then describe the complete antenna configuration.

Having resting plate current changing has nothing to do with your antenna or your tuner. You can unscrew your coax connector off back of rig and set resting plate current. Fix that first.

Terry
K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Installing an 'ugly balun' and getting rid of that stray RF really helped, but it still seems there is something mechanically wrong with the 520. I think that not being able to tune it properly is hurting my AT-230's ability to successfully tune my antenna. I noticed that on 10 and 15 the tuner works fine, but when I get to 20 or 40 it won't match at all. I also still need to ground the radio itself, I have the rig plugged into a standard wall outlet, but in my house, the wall outlets are not grounded (older home), maybe it'll help a little to get the rig properly grounded.

I wish I had the cash to have a professional look at it and realign everything for me. Either way, I'll work on testing those issues that were mentioned by Terry and see where that takes me.

Subject: [TS-520_820_530_830] RE: New Ham, Tuning issues

Hey Terry and everyone:

Sorry this took me so long, I was waiting on parts for my antenna and my AT-230 to arrive in the mail.

I tuned my TS-520 into a dummy load, using the AT-230 as a wattmeter and SWR meter. This is what I observed.

80 meters: Load just about fully meshed, CAR value: 5, 210 ma, 100 watts
40 meters: Load fully meshed, CAR value: 2.75, 210 ma, 80 watts
20 meters: Load 3/4 to meshed, CAR value: 5, 220 ma, 60 watts
15 meters: CAR value: 2.75, 210 ma, 80 watts
10 meters: Load 1/2, CAR value: 4, 210 ma, 80 watts.

I tuned into the center of the band, for voice, on each band.

I noticed that in general, when I keyed the 520 up, the needle for ma would sit at about 240 or 250 ma and then slowly drop off to 210ma on average. I also noticed I had to readjust the bias control for 60ma when I began this whole thing. It was correct the other day, but changed for some reason.

I got all of the stray RF in my shack under control and I checked my antenna and got it to about 5:1 SWR with a nice torroid on it to choke the stray RF. I got a 59 signal report

from SW Washington (I am in SW Idaho). I noticed that my tuner won't match the antenna at all on 40 meters or 20 meters, but will match on 15 and 10. I don't know if that is because of an issue with the radio, or the tuner itself, but it was an observation. I get a better SWR on 40 when I am using my antenna without the tuner. In fact, the ham in Washington couldn't hear me at all when I was passing through the tuner, but gave me the 59 without the tuner.

I opened the radio and visually inspected the components you, Terry, suggested. Nothing looks burned, the coils are still shiny and bright and none of the caps looked like they popped, everything, visually, looks clean.

What should I do now?

I was referring to checking and replacing the padder caps and the other items you described the other day. Brain was helping me tune my TS-520 and the discussion was about complications with that. You mentioned in a couple of previous posts that you were talking about a TS-830. I was concerned there was some confusion about what model of Kenwood was experiencing the issues described in this thread. If they all work the same, I'll get those padder caps tested and look at the other items referred to in your previous post.

I hope that's not more confusing, hehe. Brian knows better than I do and was able to explain the problems better than I could.

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

I am exactly sure what you are asking. If you are asking about how to load a TS520 that has no Tune Ip indication to get that initial plate current dip and is it different than a TS-830 then answer is no difference other than limiting the plate current to 200ma.

Some people with lots of experience load in CW mode. Some do this as they have a good understanding of what is going on and the pre-cautions using this method.

Others do it because the Tune position of their rig quit years ago and too lazy to fix it or dont know how to fix it.

I typically do not teach new folks to load in CW.

However if your rigs Tune position is out and you cannot get that initial plate current dip then you can do it by reducing the Car Level pot to minimum and with meter in Ip position Flip to Send and slowly bring the Car Level up to something under 100ma. Have to be careful because Ip can jump very high pretty quickly with very little more opening of the pot.

When you get say around 80ma to 100ma then adjust the plate Tune capacitor for a dip or minimum in plate current and then unkey the rig. Now ready to use the RF relative power position of the panel meter or your external wattmeter to start coupling load. Flip to Send and alternately adjust Plate Load and Plate Tune controls for max relative power on your RF meter position or approx 100 watts output on your wattmeter. Unkey the rig.

Watching the Ip meter flip to send again and if you are reasonably close to 200ma Ip you are done and ready to operate CW or SSB.

WIth a good Tune position I recommend you follow the instructions in your TS520 manual. Only confusing step is peaking the Drive which says to adjust for maximum meter deflection and everyone and I mean everyone asks "what maximum"? The ALC black box maximum or the meter full scale maximum. As I think I told you black box is meaningless at this step but OK to just peak Drive control at max range on it.

After you get that initial plate current dip in Tune mode then all the Kenwood instruction manuals direct you to load by alternately adjusting :Load and Tune controls for max RF relative power. If you have an external wattmeter leave meter in Ip and load for approx 100 watts out without exceeding 200ma.

Subject: RE: Re: [TS-520_820_530_830] New Ham, Tuning issues

Brian:

No problem with using a Key to load the rig. Just not necessary when bench testing a rig. The 830 manual contributes to this when early on they tell you to connect dummy load or antenna and connect a Key and then flip to Send and check resting plate current. However they fail to tell you to press the Key or close the slider if a straight Key. Later under Transmission section under CW header they tell you again to install a Key. Poorly written.

When you turn the Plate Load cap control CW off the full CCW position and you see the RF output power on the wattmeter go down do you then immediately adjust the Plate Tune capacitor to try to bring the RF output power back up?

Anytime the Load cap is moved open or closed you need to make a slight adjustment with the Tune capacitor to restore the tank to resonance. What happens when you do this?

Typically once the reactance of the Plate Load capacitor is close to the impedance of the load (antenna or dummy load) opening the plates (CW) any more usually does not result in anymore RF output on the wattmeter. You reach a point where opening the plates more does not result in coupling any more load. The final tubes just cannot supply any more RF Line current to the Tank.

There is no doubt that loading on 40 meters into a 50 ohm dummy load you should not be at maximum RF output with the Plate Load cap full CCW (plates fully meshed). As you suggest it is not "normal". You know that from your own TS-830.

As I mentioned this is indicative of bad fixed padder caps that are switched in on the lower bands. The reason that this is necessary is if they installed an air variable capacitor that had the necessary high level of capacitance on the lower bands it would then have a minimum capacitance with the plates completely open that would be far too high to function on higher bands. 10 meters is the biggest challenge for the designers. Same for the Plate Tune capacitor.

If you get time it would be good to see if it loads normal on 15 and 10 meters. I would try loading on all the bands and make a chart of how it behaves. Where does the plate Load cap end up for approx 100 watts output at 200ma Ip.

One other thing you should look at if comfortable is the main RF plate choke and the small VHF choke at a right angle at its base and the rf bypass cap at its base. If these show signs of overheating then will need to be replaced. The by pass cap can actually physically split the case open.

Need to have rig unplugged and let set for awhile to led bleeders discharge the HV filter caps. Then remove PA cage cover. Then connect ground jumper from top of plate choke and ground for a few seconds. Now safe to use a good flashlite and inspect these items.

I would also look at both capacitor shaft couplers at the PA cage and make sure screws are tight. Can also watch the travel and make sure full open and full close align with markings on the front panel.

Hi Terry:

Ah ha. I am a CW op so I always have had a key plugged in (but no mic). Anyway, with a key plugged in you don't get any output with the alternate procedure without closing the key for obvious reasons. I've been so used to how the radio responded when I switched over from tune to CW with a key connected that I ended up thinking the key was necessary. My bad. For me the long procedure from the manual works fine since I always have the key connected and normally have the radio in VOX mode (to save wear on the send switch) but I have a better understanding now. Thank you. I will also study the diagram to try to better understand the relationship between the load capacitor and antenna load.

This will also help Jason since I took him through the long procedure from the manual that uses a key. He can just unplug his keyer and will be able to move from tuning to loading once he has the drive and plate a resonance (peaked and dipped) without all of the additional gyrations.

Questions: This still leaves Jason's TS-520's issue with load. Even though I was using the long procedure with the key, I think the results are still accurate. He is getting a maximum output of 70w at 200ma with the load at min (fully CCW) and reducing the load capacitance (increasing the load/turning load CW) actually reduces his output. This isn't normal, right? I can simulate this on my TS-830 but it pains me. If I intentionally turn the load up too much, output falls off as I increase the load. So...I think in Jason's TS520 it is as if even at maximum capacitance (minimum load) he doesn't have enough to balance against the 50 ohm dummy load---resonance is off the minimum end of the load. Does that sound like a reasonable conclusion? Is the next step for us to try the tune up procedure on all bands and report back (your 10m suggestion from before) or is there something else that we should check first?

Thanks,
Brian (and Jason)

Subject: RE: Re: Re: [TS-520_820_530_830] RE: New Ham, Tuning issues

You dont need the key or vox or any of the gyrations you are putting your self thru to load your TS830.

The reason Ip indicates approx 60ma when you switch from Tune to CW mode is that you have the plates meshed on the Plate load cap and you are shunting the RF current around the dummy load and circulating it in the Tank.

It is OK to crack the Plate Load control open a little at initial loading so you can see 70 or 80 ma or so if that helps you.

At this point with plates fully meshed you have maximum capacitance and lowest capacitive reactance so the RF current in the tank is going to like to flow thru the plate load cap and not thru the dummy load. Sometime look at formula for Xc and you will see it is an inverse relationship. It will help you understand what I am telling you.

OK --You havent started tightening up the coupling yet and shifting the tank circuit RF circ current to the dummy load resistance. Each time you open the plates of the Load cap a little more you are decreasing the capacitance and increasing the capacitive reactance XC. This allows more current to flow in the dummy load resistor or the antenna.

When you get to full load you will have opened the Plate Load capactor to the point that the XC is approx equal to the dummy load or antenna resistance. At this point you will have used half of the stored energy in the tank and there will be equal RF current flowing thru the Plate load capacitor and the dummy load resistor. At that point with 100 watts output power there will be approx 1.4 RF amps flowing thru the Plate load cap and 1.4 RF amps flowing thru the 50 ohm dummy load.

This is all simple ohms law for parallel resistors, but not too many folks really understand what they are doing or how it works or have just never given it any serious thought.

After you make that initial plate current dip in Tune mode you do not need to do any more dip and load procedure. Only reason you do this initial dip is to get the tank circuit adjusted close to resonance so when you go to CW mode and apply full screen grid voltage to the finals you dont peg the IP meter if the tank is tuned off resonance. This could damage your finals if left keyed too long at this high Ip level.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Your very first goal is to be able to load the rig into a dummy load on all bands. Worry about using a tuner to load into a multi-band antenna after you are certain you can load "normally" in to the dummy load.

If you can load the rig successfully into dummy load with the tuner in the Bypass Mode (just using the tuner for the wattmeter/SWR meter function) then nothing is wrong with your Pi-Network in the rig unless you are at extreme ends of the Plate Load cap or the Plate Tune cap position doesnt align relatively close to the white panel marking for the band you are loading on.

If you end up having the Plate Load or Plate tune caps at odd positions to attain your 80 to 100 watts into the dummy load you may have bad fixed padder caps.

What would be "normal" is approx 90 to 100 watts into 50 ohm dummy load on all bands with exception of 10 meters (80 watts) at approx 200ma plate current and you should see very close to 1:1 SWR into your dummy load.

If you can do this then time to discuss the antenna and the tuner issues.

Again, your first effort should be to make sure the rig can load normally into a dummy load. This proves your dummy load is good, your interconnecting coax jumpers are good, and the rig is good.

If you cannot do this then no reason to attempt to use the tuner to load in to a multi-band antenna of any type.

The tuner is taking the impedance that the antenna presents at the end of whatever kind of feed line you are using and converting it to an impedance that your rigs Pi-network can match. A multiband antenna can present a wide range of impedances (combination of resistance and reactive) to your rig. The rig cannot match very high impedances (thousands of ohms) that a multiband antenna can present. If you have very high impedance at the end of the feed line in the shack then RF can be a problem in the shack. End fed can present several thousand ohms which means very high RF voltage at the input to the tuner. Sometimes need to install counter poise to resolve this situation.

Describe again what the antenna configuration is. Is this a OCF dipole or a 135 foot flat top fed with 300 ohm ladder line or open wire feeders or a random length end fed ??

It could be that the Tuner has an issue?

So tell us first if you can load rig normally into the dummy load? If so, then describe the complete antenna configuration.

Having resting plate current changing has nothing to do with your antenna or your tuner. You can unscrew your coax connector off back of rig and set resting plate current. Fix that first.

Installing an 'ugly balun' and getting rid of that stray RF really helped, but it still seems there is something mechanically wrong with the 520. I think that not being able to tune it properly is hurting my AT-230's ability to successfully tune my antenna. I noticed that on 10 and 15 the tuner works fine, but when I get to 20 or 40 it won't match at all. I also still need to ground the radio itself, I have the rig plugged into a standard wall outlet, but in my house, the wall outlets are not grounded (older home), maybe it'll help a little to get the rig properly grounded.

I wish I had the cash to have a professional look at it and realign everything for me. Either way, I'll work on testing those issues that were mentioned by Terry and see where that takes me.

Subject: [TS-520_820_530_830] RE: New Ham, Tuning issues

Hey Terry and everyone:

Sorry this took me so long, I was waiting on parts for my antenna and my AT-230 to arrive in the mail.

I tuned my TS-520 into a dummy load, using the AT-230 as a wattmeter and SWR meter. This is what I observed.

80 meters: Load just about fully meshed, CAR value: 5, 210 ma, 100 watts
40 meters: Load fully meshed, CAR value: 2.75, 210 ma, 80 watts
20 meters: Load 3/4 to meshed, CAR value: 5, 220 ma, 60 watts
15 meters: CAR value: 2.75, 210 ma, 80 watts
10 meters: Load 1/2, CAR value: 4, 210 ma, 80 watts.

I tuned into the center of the band, for voice, on each band.

I noticed that in general, when I keyed the 520 up, the needle for ma would sit at about 240 or 250 ma and then slowly drop off to 210ma on average. I also noticed I had to readjust the bias control for 60ma when I began this whole thing. It was correct the other day, but changed for some reason.

I got all of the stray RF in my shack under control and I checked my antenna and got it to about 5:1 SWR with a nice torroid on it to choke the stray RF. I got a 59 signal report

from SW Washington (I am in SW Idaho). I noticed that my tuner won't match the antenna at all on 40 meters or 20 meters, but will match on 15 and 10. I don't know if that is because of an issue with the radio, or the tuner itself, but it was an observation. I get a better SWR on 40 when I am using my antenna without the tuner. In fact, the ham in Washington couldn't hear me at all when I was passing through the tuner, but gave me the 59 without the tuner.

I opened the radio and visually inspected the components you, Terry, suggested. Nothing looks burned, the coils are still shiny and bright and none of the caps looked like they popped, everything, visually, looks clean.

What should I do now?

I am exactly sure what you are asking. If you are asking about how to load a TS520 that has no Tune Ip indication to get that initial plate current dip and is it different than a TS-830 then answer is no difference other than limiting the plate current to 200ma.

Some people with lots of experience load in CW mode. Some do this as they have a good understanding of what is going on and the pre-cautions using this method.

Others do it because the Tune position of their rig quit years ago and too lazy to fix it or dont know how to fix it.

I typically do not teach new folks to load in CW.

However if your rigs Tune position is out and you cannot get that initial plate current dip then you can do it by reducing the Car Level pot to minimum and with meter in Ip position Flip to Send and slowly bring the Car Level up to something under 100ma. Have to be careful because Ip can jump very high pretty quickly with very little more opening of the pot.

When you get say around 80ma to 100ma then adjust the plate Tune capacitor for a dip or minimum in plate current and then unkey the rig. Now ready to use the RF relative power position of the panel meter or your external wattmeter to start coupling load. Flip to Send and alternately adjust Plate Load and Plate Tune controls for max relative power on your RF meter position or approx 100 watts output on your wattmeter. Unkey the rig.

Watching the Ip meter flip to send again and if you are reasonably close to 200ma Ip you are done and ready to operate CW or SSB.

WIth a good Tune position I recommend you follow the instructions in your TS520 manual. Only confusing step is peaking the Drive which says to adjust for maximum meter deflection and everyone and I mean everyone asks "what maximum"? The ALC black box maximum or the meter full scale maximum. As I think I told you black box is meaningless at this step but OK to just peak Drive control at max range on it.

After you get that initial plate current dip in Tune mode then all the Kenwood instruction manuals direct you to load by alternately adjusting :Load and Tune controls for max RF relative power. If you have an external wattmeter leave meter in Ip and load for approx 100 watts out without exceeding 200ma.

Subject: RE: Re: [TS-520_820_530_830] New Ham, Tuning issues

Brian:

No problem with using a Key to load the rig. Just not necessary when bench testing a rig. The 830 manual contributes to this when early on they tell you to connect dummy load or antenna and connect a Key and then flip to Send and check resting plate current. However they fail to tell you to press the Key or close the slider if a straight Key. Later under Transmission section under CW header they tell you again to install a Key. Poorly written.

When you turn the Plate Load cap control CW off the full CCW position and you see the RF output power on the wattmeter go down do you then immediately adjust the Plate Tune capacitor to try to bring the RF output power back up?

Anytime the Load cap is moved open or closed you need to make a slight adjustment with the Tune capacitor to restore the tank to resonance. What happens when you do this?

Typically once the reactance of the Plate Load capacitor is close to the impedance of the load (antenna or dummy load) opening the plates (CW) any more usually does not result in anymore RF output on the wattmeter. You reach a point where opening the plates more does not result in coupling any more load. The final tubes just cannot supply any more RF Line current to the Tank.

There is no doubt that loading on 40 meters into a 50 ohm dummy load you should not be at maximum RF output with the Plate Load cap full CCW (plates fully meshed). As you suggest it is not "normal". You know that from your own TS-830.

As I mentioned this is indicative of bad fixed padder caps that are switched in on the lower bands. The reason that this is necessary is if they installed an air variable capacitor that had the necessary high level of capacitance on the lower bands it would then have a minimum capacitance with the plates completely open that would be far too high to function on higher bands. 10 meters is the biggest challenge for the designers. Same for the Plate Tune capacitor.

If you get time it would be good to see if it loads normal on 15 and 10 meters. I would try loading on all the bands and make a chart of how it behaves. Where does the plate Load cap end up for approx 100 watts output at 200ma Ip.

One other thing you should look at if comfortable is the main RF plate choke and the small VHF choke at a right angle at its base and the rf bypass cap at its base. If these show signs of overheating then will need to be replaced. The by pass cap can actually physically split the case open.

Need to have rig unplugged and let set for awhile to led bleeders discharge the HV filter caps. Then remove PA cage cover. Then connect ground jumper from top of plate choke and ground for a few seconds. Now safe to use a good flashlite and inspect these items.

I would also look at both capacitor shaft couplers at the PA cage and make sure screws are tight. Can also watch the travel and make sure full open and full close align with markings on the front panel.

Subject: RE: Re: Re: [TS-520_820_530_830] RE: New Ham, Tuning issues

You dont need the key or vox or any of the gyrations you are putting your self thru to load your TS830.

The reason Ip indicates approx 60ma when you switch from Tune to CW mode is that you have the plates meshed on the Plate load cap and you are shunting the RF current around the dummy load and circulating it in the Tank.

It is OK to crack the Plate Load control open a little at initial loading so you can see 70 or 80 ma or so if that helps you.

At this point with plates fully meshed you have maximum capacitance and lowest capacitive reactance so the RF current in the tank is going to like to flow thru the plate load cap and not thru the dummy load. Sometime look at formula for Xc and you will see it is an inverse relationship. It will help you understand what I am telling you.

OK --You havent started tightening up the coupling yet and shifting the tank circuit RF circ current to the dummy load resistance. Each time you open the plates of the Load cap a little more you are decreasing the capacitance and increasing the capacitive reactance XC. This allows more current to flow in the dummy load resistor or the antenna.

When you get to full load you will have opened the Plate Load capactor to the point that the XC is approx equal to the dummy load or antenna resistance. At this point you will have used half of the stored energy in the tank and there will be equal RF current flowing thru the Plate load capacitor and the dummy load resistor. At that point with 100 watts output power there will be approx 1.4 RF amps flowing thru the Plate load cap and 1.4 RF amps flowing thru the 50 ohm dummy load.

This is all simple ohms law for parallel resistors, but not too many folks really understand what they are doing or how it works or have just never given it any serious thought.

Topic: 44440 Message: 45000

You do not "tune down the wattage". Always tune the transmitter for
maximum power output. Never reduce output power by adjusting the "LOAD"
control!

Use the CAR control in CW to control output power level.

If you need to reduce power in sideband use the battery and pot circuit
found in the group's "File" section to apply a "negative" DC voltage to
the external "ALC" connection.

Topic: 44969 Message: 45001

Initially the Heathkit Apache TX-1 did not have a final cage fan. Heath added that later on but the fan was small. The final amplifier, a pair of 6146As, ran much hotter, AM mode, than the KW hybrids. The small fan Heath used ran from a small 120VAC phonograph type motor. The motor in my Apache was bad, turned at less than half speed. I trashed the fan assembly and installed a larger 120VAC muffin fan. I had the fan blow air into the final cage. This arrangement did not produce an excessive amount of duty collection on the fan blade, fan shroud, or the final tubes and components. Cleaning the fan and final amplifier was easy, canned air removed any dust collected on the fan and final tubes and components.

I did the same thing by attaching a small 12VDC muffin fan to the rear portion of the final cage with my Drake T4XB and T4XC transmitters. The fan blew air into the final cage and the fan was powered from a half wave rectifier from the 12VAC filament supply. I used a single silicon diode and an 8ufd 25VDC filter capacitor to provide the 12VDC for the fan. The fan ran at about the same speed as the KW hybrid fans. Cleaning of the fan and final enclosure takes about 5 minutes one the covers are removed.

Subject: Re: [TS-520_820_530_830] RE: 520s send/rec switch not working

Steve,

  Welcome to the phrase "CB HACK" or "FREE BANDING." Without going into detail..the "mod" allows the rig to receive and transmit
in the CB and other non-ham band areas Generally, from about the low 26Mhz area and up above 29Mhz. This mod is usually easy to remove, unless the
hacker has cut some diodes on the "digital readout" board...then it could become a problem re-doing the diode(s) leads. I have also seen
the PLL board hack...but I have not seen it as much as the above mentioned. Also, the famous "QRO" mode could have been done to get
every last milliwatt of power out of the finals...this is stupid and causes damage to numerous components. The most common QRO mod is moving
1 wire from the "210" post to the "300" post on the rectifier board. This raises the voltage to the final tubes
screens...thus "more power." Also, changing
the value of the 470 ohm resistor..which I think is R-11 on the rectifier board. Compare the wires you SEE to the wiring schematic.

 As far as the band "blanking out"...could be a couple of problems...MOST common is the "wiper" inside the VFO unit has gotten some gunk/corrosion
on it. The VFO is easy to remove..using the 4 screws on the front. Pull out slowly..as there are wires connected to it for the voltage/signals and for the
lights. I usually do this with the rigs top and bottom covers removed....rig UNPLUGGED from the power(my standard disclaimer). Remove the dial lamps and,
the connector on the rear of the VFO...it just un-plugs. Remove the screws holding the cover in place...the wiper is at the rear..use some contact cleaner...operate
the VFO through its travel several times...blow off with "canned air" and repeat once...you can reconnect the connector on the
rear...turn rig back on and check for
proper operation before fully reinstalling it. Try this first and let us know

Subject: [TS-520_820_530_830] RE: 520s send/rec switch not working

I hate to add to my last topic with a different topic. But I am having problems finding the post button. Is it me or is this new format a problem for everybody.

I just came into a 530s. there is a 28MHZ mod that i would like to rid myself of. looks obvious on the surface. a 2 position switch and 4 wires making and breaking some wires going to the VFO board. Anybody know if there are more mods to be on the look out for, maybe some that are not as obvious as a switch and bell wire being strung here and there. The digital display will also blank out from time to time, either when band switching or just tuning across the dial on some bands.

I am looking for info on the 530s including how to do an alignment, etc..the basic stuff.
but like I said before I am having problems navigating this forum now.
So far it seems to tune up on 20m but not so much on 40m. made some contacts, VFO seems to be on target, audio is good. Anything to look for that 530s are known for? My Other rig is the 520s

again thanks for the input guys

steve

---In ts-520_820_530_830@yahoogroups.com, <yioutta_99@...> wrote:

thats probably what fixed it. LOL.
Then I went to watch TV. Good show on Niagra falls was on, then all the water came through the screen.

I picked up a cheap 530 today. and I am hunting info on it now it has some problems..
the cheap part.

Thanks Joe..and the rest of the thread.

Tonight the switched worked. overtime and on 80 meters as well as 20 meters. Either I have an intermindant or perhaps i didnt give the heater enough time to warm up. But now that its working, its hard to trouble shoot. If i have to go in for another reason, I'll check the relay and get it cleaned up..or replaced. The good news is I went and got some more canned air for the occasion and it was on sale for 10 bucks for 3 cans. so now i am well stocked.

Thanks everybody.

steve

Greeting Group

  Your caring Group Co-owner here...have any of the members here, had messages returned in the recent past and, up to now, by the yahoo "MAILER-DAEMON"
as undeliverable to the "TS-520_.....830@yahoogroups.com?" I tried the other day and twice since, to answer member "yiotta_99" regarding
the "cb hack" he found in a newly acquired rig...the msg came back...maybe "yahoo" is peed-off and messing with us(me). I have sent
several messages to other well known members here...and they have disappeared..or came back as "undeliverable" to this group. Nothing
has changed as far as any setting...etc...my regular email...etc. ...is ok.

  Some members here(very few actually) are on "moderate," which means that either me-wb7uqu, Gordon -n6wk, Mike-w5rkl or, the other group "demi-gods" must "approve" the message/content before it is posted here which, depending on the time of day or, day of the week, maybe delayed. I know that the "powers that be" strive to review new member requests, review "moderated" messages...and take care of this groups business.

  So...I may be QRT, until I can get an answer from "yahoo" about what's going on. So far, "they" have not seen fit to respond to my inquiry.

  Let's see IF this msg gets posted.............

Joe,

I have seen messages, some of mine, have taken quite a while to get posted. This doesn't happen all the times but it does happen. This has occurred not only after Yahoo made the change but it also has occurred before they made the change. I have even seen messages that appear to get "lost" in the "bit bucket" then after a few days, even as long as a week, suddenly appear.

I can't say with any certainty what is causing this, only Yahoo knows. Don't expect a quick response from Yahoo, they are slow to respond. Yahoo took a couple of weeks to respond to my comments about their bad choice for change.

Ok my Apache did not have a fan and many other 6146 rigs of that era did not.

Point I was trying to make is no reason to remove the KW fan and adapt any other higher volume fan to it as was reported to this forum. Running hot is a very subjective thing. Keeping the Kenwood fan clean, lubed and the cabinet vent holes unobstructed is all you need for Hybrid to perform at its design ratings for the design modes.

Just my opinion based on personal experience and seeing TS520 rigs with original Matsushita tubes and no signs of overheating in the PA cage.

If people want to mod the rig with higher volume fans it surely wont hurt anything other than perhaps cause dust build up on all parts in PA cage to accumulate at much faster rate. I have seen rigs with greasy dust thickly deposited on the tube glass envelopes that surely was impeding the heat transfer from glass to air.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Initially the Heathkit Apache TX-1 did not have a final cage fan. Heath added that later on but the fan was small. The final amplifier, a pair of 6146As, ran much hotter, AM mode, than the KW hybrids. The small fan Heath used ran from a small 120VAC phonograph type motor. The motor in my Apache was bad, turned at less than half speed. I trashed the fan assembly and installed a larger 120VAC muffin fan. I had the fan blow air into the final cage. This arrangement did not produce an excessive amount of duty collection on the fan blade, fan shroud, or the final tubes and components. Cleaning the fan and final amplifier was easy, canned air removed any dust collected on the fan and final tubes and components.

I did the same thing by attaching a small 12VDC muffin fan to the rear portion of the final cage with my Drake T4XB and T4XC transmitters. The fan blew air into the final cage and the fan was powered from a half wave rectifier from the 12VAC filament supply. I used a single silicon diode and an 8ufd 25VDC filter capacitor to provide the 12VDC for the fan. The fan ran at about the same speed as the KW hybrid fans. Cleaning of the fan and final enclosure takes about 5 minutes one the covers are removed.

Mike W5RKL

On 10/1/2013 1:03 PM, wagstw46@... wrote:

If you read the RCA 6146 tube data sheet you will see that max envelope temperature is 260 degrees C and that the tube is designed to run in free air with no additional cooling required.

In the old boatanchor days of Heath Apaches and Johnson Vikings and many similar transmitters no cooling fan was installed by the manufacturer. The later Heath SB and HW series transceivers had no cooling fans.

In those old boatanchors there was a lot of open space around the 6146 finals. In the transceivers to follow a small PA cage was the norm. One of first thing most of us did was to sit a muffin or whisper fan on top the PA cage and pull air from that PA cage. All kinds of tricks to slow them down and rubber mount them to quiet them down. We did this without any evidence that the fans were needed or would increase the life of the finals. No empirical data was compiled. Just seemed like needed a fan and a fan couldnt hurt. I did on my Heath transceivers.

However never gave it a thought to put a cooling fan on the Apache or Viking.

Kenwood gave us a nice slow quiet fan and it is more than adequate to ensure we dont exceed the 6146 tube envelop temperatures and ensure long life if we load and operate the radio properly for each mode we run.

Mike give very good advice. Keep fan cleaned and lubed and as he says do not stack other gear on or around the rig in an enclosed mounting position.

I cannot ever envision a time I would need to increase the cooling capacity of the factory fan. I get rigs on the bench often that have the original S2001A finals and no after market air mover installed.

Hi Joe, Mike & all,

Joe, Yours is not an isolated case I have had the same happen and in addition I've had an entire 2 to 3 days messages from a number of groups show up as new after they had been read & deleted from email. This NEO thing stinks big-time but I doubt Yahoo will ever admit responsibility, or their mistake in rolling-out NEO in this half(?)-ready condition. If past performance is any guide anyway.

Well... enough grousing. Back to the program already in progress.

Vy 73,
mjsyn(Mike)

Retrying this again as he did not get posted

Bob
The rig is a ts830.
They soldered a two wire shielded cable from the bottom of the PLL board [conn 5 and routed it out to the back of the rig to a rca phono plug.
Conn 5 on the PLL board is for VFO input
I would like to know what they had in mind when they installed this plug.

Don: Actually, it did get posted a few hours ago. I am researching into your question, but have found nothing as of yet. Please check this group's archieves, and I will respond if/when I found out something. Good luck with this..I also have an 830s

TO GROUP: I have been seeing several messages that owner stated were never posted...but they were

45010. TS-830S L41 Coil rewinding

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-02 05:25:16 UTC
From: <n6wk@...>
Topic: 45010 Message: 45010

I am now rewinding the L-41 Coils. I charge $20.00 each.. EXCHANGE. Meaning, I charge $20.00 for the rewound coil plus your old Coil in exchange.
I presently have two coils available that are rewound and tested.
I will NOT sell a coil without an exchange one in return.
If interested, contact me OFF-list at N6WK at N6WK.COM

45011. RE: RE: New Ham, Tuning issues

Topic: 44440 Message: 45011

No reason to worry about 5:1 swr until we know what kind of antenna configuration and what freq he is trying to load it on. May be perfectly understandable. Ever see the SWR loading a typical G5RV on 15 or 17 meters?

My guess is with all the RF in the shack may be using end fed antenna? May be using an OCF dipole but I have used them and no problems with RF in shack but I feed with 4:1 current balun at the offset feed point.

All this is just speculation until we know what he is using.

After he gets rig to load properly into 50 ohm dummy load we can all jump in and help resolve the antenna and tuner issues that may exist.

Terry K9TW

5 : 1 SWR ?

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Your very first goal is to be able to load the rig into a dummy load on all bands. Worry about using a tuner to load into a multi-band antenna after you are certain you can load "normally" in to the dummy load.

If you can load the rig successfully into dummy load with the tuner in the Bypass Mode (just using the tuner for the wattmeter/SWR meter function) then nothing is wrong with your Pi-Network in the rig unless you are at extreme ends of the Plate Load cap or the Plate Tune cap position doesnt align relatively close to the white panel marking for the band you are loading on.

If you end up having the Plate Load or Plate tune caps at odd positions to attain your 80 to 100 watts into the dummy load you may have bad fixed padder caps.

What would be "normal" is approx 90 to 100 watts into 50 ohm dummy load on all bands with exception of 10 meters (80 watts) at approx 200ma plate current and you should see very close to 1:1 SWR into your dummy load.

If you can do this then time to discuss the antenna and the tuner issues.

Again, your first effort should be to make sure the rig can load normally into a dummy load. This proves your dummy load is good, your interconnecting coax jumpers are good, and the rig is good.

If you cannot do this then no reason to attempt to use the tuner to load in to a multi-band antenna of any type.

The tuner is taking the impedance that the antenna presents at the end of whatever kind of feed line you are using and converting it to an impedance that your rigs Pi-network can

match. A multiband antenna can present a wide range of impedances (combination of resistance and reactive) to your rig. The rig cannot match very high impedances (thousands of ohms) that a multiband antenna can present. If you have very high impedance at the end of the feed line in the shack then RF can be a problem in the shack. End fed can present several thousand ohms which means very high RF voltage at the input to the tuner. Sometimes need to install counter poise to resolve this situation.

Describe again what the antenna configuration is. Is this a OCF dipole or a 135 foot flat top fed with 300 ohm ladder line or open wire feeders or a random length end fed ??

It could be that the Tuner has an issue?

So tell us first if you can load rig normally into the dummy load? If so, then describe the complete antenna configuration.

Having resting plate current changing has nothing to do with your antenna or your tuner. You can unscrew your coax connector off back of rig and set resting plate current. Fix that first.

Subject: [TS-520_820_530_830] RE: New Ham, Tuning issues

Hey Terry and everyone:

Sorry this took me so long, I was waiting on parts for my antenna and my AT-230 to arrive in the mail.

I tuned my TS-520 into a dummy load, using the AT-230 as a wattmeter and SWR meter. This is what I observed.

80 meters: Load just about fully meshed, CAR value: 5, 210 ma, 100 watts
40 meters: Load fully meshed, CAR value: 2.75, 210 ma, 80 watts
20 meters: Load 3/4 to meshed, CAR value: 5, 220 ma, 60 watts
15 meters: CAR value: 2.75, 210 ma, 80 watts
10 meters: Load 1/2, CAR value: 4, 210 ma, 80 watts.

I tuned into the center of the band, for voice, on each band.

I noticed that in general, when I keyed the 520 up, the needle for ma would sit at about 240 or 250 ma and then slowly drop off to 210ma on average. I also noticed I had to readjust the bias control for 60ma when I began this whole thing. It was correct the other day, but changed for some reason.

I got all of the stray RF in my shack under control and I checked my antenna and got it to about 5:1 SWR with a nice torroid on it to choke the stray RF. I got a 59 signal report from SW Washington (I am in SW Idaho). I noticed that my tuner won't match the antenna at all on 40 meters or 20 meters, but will match on 15 and 10. I don't know if that is because of an issue with the radio, or the tuner itself, but it was an observation. I get a better SWR on 40 when I am using my antenna without the tuner. In fact, the ham in Washington couldn't hear me at all when I was passing through the tuner, but gave me the 59 without the tuner.

I opened the radio and visually inspected the components you, Terry, suggested. Nothing looks burned, the coils are still shiny and bright and none of the caps looked like they popped, everything, visually, looks clean.

What should I do now?

I hope that's not more confusing, hehe. Brian knows better than I do and was able to explain the problems better than I could.

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

I am exactly sure what you are asking. If you are asking about how to load a TS520 that has no Tune Ip indication to get that initial plate current dip and is it different than a TS-830 then answer is no difference other than limiting the plate current to 200ma.

Some people with lots of experience load in CW mode. Some do this as they have a good understanding of what is going on and the pre-cautions using this method.

Others do it because the Tune position of their rig quit years ago and too lazy to fix it or dont know how to fix it.

I typically do not teach new folks to load in CW.

However if your rigs Tune position is out and you cannot get that initial plate current dip then you can do it by reducing the Car Level pot to minimum and with meter in Ip position Flip to Send and slowly bring the Car Level up to something under 100ma. Have to be careful because Ip can jump very high pretty quickly with very little more opening of the pot.

When you get say around 80ma to 100ma then adjust the plate Tune capacitor for a dip or minimum in plate current and then unkey the rig. Now ready to use the RF relative power position of the panel meter or your external wattmeter to start coupling load. Flip to Send and alternately adjust Plate Load and Plate Tune controls for max relative power on your RF meter position or approx 100 watts output on your wattmeter. Unkey the rig.

Watching the Ip meter flip to send again and if you are reasonably close to 200ma Ip you are done and ready to operate CW or SSB.

WIth a good Tune position I recommend you follow the instructions in your TS520 manual. Only confusing step is peaking the Drive which says to adjust for maximum meter deflection and everyone and I mean everyone asks "what maximum"? The ALC black box maximum or the meter full scale maximum. As I think I told you black box is meaningless at this step but OK to just peak Drive control at max range on it.

After you get that initial plate current dip in Tune mode then all the Kenwood instruction manuals direct you to load by alternately adjusting :Load and Tune controls for max RF relative power. If you have an external wattmeter leave meter in Ip and load for approx 100 watts out without exceeding 200ma.

Subject: RE: Re: [TS-520_820_530_830] New Ham, Tuning issues

Brian:

No problem with using a Key to load the rig. Just not necessary when bench testing a rig. The 830 manual contributes to this when early on they tell you to connect dummy load or antenna and connect a Key and then flip to Send and check resting plate current. However they fail to tell you to press the Key or close the slider if a straight Key. Later under Transmission section under CW header they tell you again to install a Key. Poorly written.

When you turn the Plate Load cap control CW off the full CCW position and you see the RF output power on the wattmeter go down do you then immediately adjust the Plate Tune capacitor to try to bring the RF output power back up?

Anytime the Load cap is moved open or closed you need to make a slight adjustment with the Tune capacitor to restore the tank to resonance. What happens when you do this?

Typically once the reactance of the Plate Load capacitor is close to the impedance of the load (antenna or dummy load) opening the plates (CW) any more usually does not result in anymore RF output on the wattmeter. You reach a point where opening the plates more does not result in coupling any more load. The final tubes just cannot supply any more RF Line current to the Tank.

There is no doubt that loading on 40 meters into a 50 ohm dummy load you should not be at maximum RF output with the Plate Load cap full CCW (plates fully meshed). As you suggest it is not "normal". You know that from your own TS-830.

As I mentioned this is indicative of bad fixed padder caps that are switched in on the lower bands. The reason that this is necessary is if they installed an air variable capacitor that had the necessary high level of capacitance on the lower bands it would then have a minimum capacitance with the plates completely open that would be far too high to function on higher bands. 10 meters is the biggest challenge for the designers. Same for the Plate Tune capacitor.

If you get time it would be good to see if it loads normal on 15 and 10 meters. I would try loading on all the bands and make a chart of how it behaves. Where does the plate Load cap end up for approx 100 watts output at 200ma Ip.

One other thing you should look at if comfortable is the main RF plate choke and the small VHF choke at a right angle at its base and the rf bypass cap at its base. If these show signs of overheating then will need to be replaced. The by pass cap can actually physically split the case open.

Need to have rig unplugged and let set for awhile to led bleeders discharge the HV filter caps. Then remove PA cage cover. Then connect ground jumper from top of plate choke and ground for a few seconds. Now safe to use a good flashlite and inspect these items.

I would also look at both capacitor shaft couplers at the PA cage and make sure screws are tight. Can also watch the travel and make sure full open and full close align with markings on the front panel.

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Hi Terry:

Ah ha. I am a CW op so I always have had a key plugged in (but no mic). Anyway, with a key plugged in you don't get any output with the alternate procedure without closing the key for obvious reasons. I've been so used to how the radio responded when I switched over from tune to CW with a key connected that I ended up thinking the key was necessary. My bad. For me the long procedure from the manual works fine since I always have the key connected and normally have the radio in VOX mode (to save wear on the send switch) but I have a better understanding now. Thank you. I will also study the diagram to try to better understand the relationship between the load capacitor and antenna load.

This will also help Jason since I took him through the long procedure from the manual that uses a key. He can just unplug his keyer and will be able to move from tuning to loading once he has the drive and plate a resonance (peaked and dipped) without all of the additional gyrations.

Questions: This still leaves Jason's TS-520's issue with load. Even though I was using the long procedure with the key, I think the results are still accurate. He is getting a maximum output of 70w at 200ma with the load at min (fully CCW) and reducing the load capacitance (increasing the load/turning load CW) actually reduces his output. This isn't normal, right? I can simulate this on my TS-830 but it pains me. If I intentionally turn the load up too much, output falls off as I increase the load. So...I think in Jason's TS520 it is as if even at maximum capacitance (minimum load) he doesn't have enough to balance against the 50 ohm dummy load---resonance is off the minimum end of the load. Does that sound like a reasonable conclusion? Is the next step for us to try the tune up procedure on all bands and report back (your 10m suggestion from before) or is there something else that we should check first?

Thanks,
Brian (and Jason)

Subject: RE: Re: Re: [TS-520_820_530_830] RE: New Ham, Tuning issues

You dont need the key or vox or any of the gyrations you are putting your self thru to load your TS830.

The reason Ip indicates approx 60ma when you switch from Tune to CW mode is that you have the plates meshed on the Plate load cap and you are shunting the RF current around the dummy load and circulating it in the Tank.

It is OK to crack the Plate Load control open a little at initial loading so you can see 70 or 80 ma or so if that helps you.

At this point with plates fully meshed you have maximum capacitance and lowest capacitive reactance so the RF current in the tank is going to like to flow thru the plate load cap and not thru the dummy load. Sometime look at formula for Xc and you will see it is an inverse relationship. It will help you understand what I am telling you.

OK --You havent started tightening up the coupling yet and shifting the tank circuit RF circ current to the dummy load resistance. Each time you open the plates of the Load cap a little more you are decreasing the capacitance and increasing the capacitive reactance XC. This allows more current to flow in the dummy load resistor or the antenna.

When you get to full load you will have opened the Plate Load capactor to the point that the XC is approx equal to the dummy load or antenna resistance. At this point you wc ?Oz?□? □??ty

Topic: 44440 Message: 45012

I am still working on testing those items you pointed out, Terry. I am trying to get a hold of a voltmeter to see what those values are.

As far as my antenna goes, it's a 40 meter center-fed dipole, each leg is cut at 32 feet. The dipole has a center insulator with a line isolator attached. The isolator is what ended my 'RF in the shack' issues. The dipole is mounted in an inverted V formation, with the center insulator hoisted up on a PVC pipe, 17 feet into the air (about as high as I can get it on my property). both ends of the V are mounted about 5 feet off the ground, the angle is greater than 90 degrees. The feedline is 25 feet of RG-213U coming off of my roof and into my house and connecting to my AT-230.

After adding the line isolator, the SWR is 5:1 at 7.200mhz,

My rig is also now grounded, electrically, to my house's electrical grounding rod, with a 5 ft piece of heavy gauge wire. The AT-230 is also grounded, with a strap connecting the tuner directly to my TS520. The tuner is connected to the 520 and the 520 is connected to the ground rod.

My house is surrounded, basically, by the power company's high voltage wires. The furthest away I could get the dipole from these HV wires is about 15 feet, maybe. I can't get any further away from the power company's lines than that. I haven't heard any noise on the 520 from those power lines, but I don't know if they might be an issue as well.

I just wanted to get that thrown out there for you to chew on, while I get a voltmeter to test the rig.

The tuner will not tune the antenna on 3.5 mhz, 7mhz or 14 mhz, but it tunes on 21, 28 and 29 mhz. When I try to tune the antenna on 7 mhz (40 meters), I get an electrical arcing noise from the 520. I also noticed that if I calibrate the tuner for too long, to check my antenna's SWR, it will blow the fuse in the TS520. Maybe that's normal, but I am not sure so I thought I would mention it.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

No reason to worry about 5:1 swr until we know what kind of antenna configuration and what freq he is trying to load it on. May be perfectly understandable. Ever see the SWR loading a typical G5RV on 15 or 17 meters?

My guess is with all the RF in the shack may be using end fed antenna? May be using an OCF dipole but I have used them and no problems with RF in shack but I feed with 4:1 current balun at the offset feed point.

All this is just speculation until we know what he is using.

After he gets rig to load properly into 50 ohm dummy load we can all jump in and help resolve the antenna and tuner issues that may exist.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

5 : 1 SWR ?

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Your very first goal is to be able to load the rig into a dummy load on all bands. Worry about using a tuner to load into a multi-band antenna after you are certain you can load "normally" in to the dummy load.

If you can load the rig successfully into dummy load with the tuner in the Bypass Mode (just using the tuner for the wattmeter/SWR meter function) then nothing is wrong with your Pi-Network in the rig unless you are at extreme ends of the Plate Load cap or the Plate Tune cap position doesnt align relatively close to the white panel marking for the band you are loading on.

If you end up having the Plate Load or Plate tune caps at odd positions to attain your 80 to 100 watts into the dummy load you may have bad fixed padder caps.

What would be "normal" is approx 90 to 100 watts into 50 ohm dummy load on all bands with exception of 10 meters (80 watts) at approx 200ma plate current and you should see very close to 1:1 SWR into your dummy load.

If you can do this then time to discuss the antenna and the tuner issues.

Again, your first effort should be to make sure the rig can load normally into a dummy load. This proves your dummy load is good, your interconnecting coax jumpers are good, and the rig is good.

If you cannot do this then no reason to attempt to use the tuner to load in to a multi-band antenna of any type.

The tuner is taking the impedance that the antenna presents at the end of whatever kind of feed line you are using and converting it to an impedance that your rigs Pi-network can match. A multiband antenna can present a wide range of impedances (combination of resistance and reactive) to your rig. The rig cannot match very high impedances (thousands of ohms) that a multiband antenna can present. If you have very high impedance at the end of the feed line in the shack then RF can be a problem in the shack. End fed can present several thousand ohms which means very high RF voltage at the input to the tuner. Sometimes need to install counter poise to resolve this situation.

Describe again what the antenna configuration is. Is this a OCF dipole or a 135 foot flat top fed with 300 ohm ladder line or open wire feeders or a random length end fed ??

It could be that the Tuner has an issue?

So tell us first if you can load rig normally into the dummy load? If so, then describe the complete antenna configuration.

Having resting plate current changing has nothing to do with your antenna or your tuner. You can unscrew your coax connector off back of rig and set resting plate current. Fix that first.

Brian:

No problem with using a Key to load the rig. Just not necessary when bench testing a rig. The 830 manual contributes to this when early on they tell you to connect dummy load or antenna and connect a Key and then flip to Send and check resting plate current. However they fail to tell you to press the Key or close the slider if a straight Key. Later under Transmission section under CW header they tell you again to install a Key. Poorly written.

When you turn the Plate Load cap control CW off the full CCW position and you see the RF output power on the wattmeter go down do you then immediately adjust the Plate Tune capacitor to try to bring the RF output power back up?

Anytime the Load cap is moved open or closed you need to make a slight adjustment with the Tune capacitor to restore the tank to resonance. What happens when you do this?

Typically once the reactance of the Plate Load capacitor is close to the impedance of the load (antenna or dummy load) opening the plates (CW) any more usually does not result in anymore RF output on the wattmeter. You reach a point where opening the plates more does not result in coupling any more load. The final tubes just cannot supply any more RF Line current to the Tank.

There is no doubt that loading on 40 meters into a 50 ohm dummy load you should not be at maximum RF output with the Plate Load cap full CCW (plates fully meshed). As you suggest it is not "normal". You know that from your own TS-830.

As I mentioned this is indicative of bad fixed padder caps that are switched in on the lower bands. The reason that this is necessary is if they installed an air variable capacitor that had the necessary high level of capacitance on the lower bands it would then have a minimum capacitance with the plates completely open that would be far too high to function on higher bands. 10 meters is the biggest challenge for the designers. Same for the Plate Tune capacitor.

If you get time it would be good to see if it loads normal on 15 and 10 meters. I would try loading on all the bands and make a chart of how it behaves. Where does the plate Load cap end up for approx 100 watts output at 200ma Ip.

One other thing you should look at if comfortable is the main RF plate choke and the small VHF choke at a right angle at its base and the rf bypass cap at its base. If these show signs of overheating then will need to be replaced. The by pass cap can actually physically split the case open.

Need to have rig unplugged and let set for awhile to led bleeders discharge the HV filter caps. Then remove PA cage cover. Then connect ground jumper from top of plate choke and ground for a few seconds. Now safe to use a good flashlite and inspect these items.

I would also look at both capacitor shaft couplers at the PA cage and make sure screws are tight. Can also watch the travel and make sure full open and full close align with markings on the front panel.

Hi Terry:

Ah ha. I am a CW op so I always have had a key plugged in (but no mic). Anyway, with a key plugged in you don't get any output with the alternate procedure without closing the key for obvious reasons. I've been so used to how the radio responded when I switched over from tune to CW with a key connected that I ended up thinking the key was necessary. My bad. For me the long procedure from the manual works fine since I always have the key connected and normally have the radio in VOX mode (to save wear on the send switch) but I have a better understanding now. Thank you. I will also study the diagram to try to better understand the relationship between the load capacitor and antenna load.

This will also help Jason since I took him through the long procedure from the manual that uses a key. He can just unplug his keyer and will be able to move from tuning to loading once he has the drive and plate a resonance (peaked and dipped) without all of the additional gyrations.

Questions: This still leaves Jason's TS-520's issue with load. Even though I wa1?,j□?????m???jם

First thing. It is ok to place a 1:1 choke in line at the center insulator but can tell you hams ran resonant dipoles for many many years with the coax directly feeding each leg of the dipole and never knew there was any current on outside of the shield and never caused any RF problems in the shack. At this point dont worry about that.

467/7.2mhz = 64 foot 10 inches or 32 foot 5 inches each leg.

Your 64 foot = 467/64 = 7.297mhz. Your antenna is too short for 7.2 mhz assuming that is where you want it to be resonant at. You can easily add about 6 inches to each end and just let it hang done at the end insulator eye. No need to remove and add wire at this point.

Was 7.200 your objective? Center of phone band? Center of the allocation? If you insist on using Tuner and having 1:1 across the band then just cut it for 7.150mhz.

You can easily determine whether you need to add or remove wire by loading into it on either side of where you now have this "low or best" SWR of 5:1 and see which direction causes lower SWR. .

If the SWR gets lower as you move up in frequency you know antenna is too short and you need to add wire to each leg. If SWR gets better as you move down in frequency then you know antenna is too long and you need to remove wire on each leg.

Make sure you check my math.

Using a 40 meter antenna on 80 meters is not going to be very efficient.

Should never get an electrical arcing noise in PA cage when loading a 40 meter dipole on 40 meters. Most common reason for arcing is Plate load cap arcing over but you almost need to have an open at the SO-239 to get high enough RF voltage.

Just remove this Tuner and use the RF detector position and load your radio exactly as the manual says to do. Move up to 7.297mhz and load there. After you get the initial dip in Tune mode then go to CW mode and put meter in RF and load by alternately adjusting the Plate Load and Tune controls for maximum relative power indication on your meter. Place meter switch back to Ip and make sure not exceeding approx 200 ma. The rig is loaded.

If you cannot load this radio without a Tuner into a dummy load on 40 meters or into a 40 meter dipole there is no point in adding a Tuner into the equation. If rig arcs over loading into dummy load and or antenna check your coax jumpers. May have a bad jumper. Takes a very high VSWR to produce very high RF voltage across the Plate Load cap. Highest would be if you have an open. If you have an open the rig will try to load into it and not easy for you to recognize that by looking at RF or IP meter position unless you have experience.

When you can load normally on all bands into the dummy load and into the 40 meter dipole on 40 meters then time to see if you have a good Tuner.

I am still working on testing those items you pointed out, Terry. I am trying to get a hold of a voltmeter to see what those values are.

As far as my antenna goes, it's a 40 meter center-fed dipole, each leg is cut at 32 feet. The dipole has a center insulator with a line isolator attached. The isolator is what ended my 'RF in the shack' issues. The dipole is mounted in an inverted V formation, with the center insulator hoisted up on a PVC pipe, 17 feet into the air (about as high as I can get it on my property). both ends of the V are mounted about 5 feet off the ground, the angle is greater than 90 degrees. The feedline is 25 feet of RG-213U coming off of my roof and into my house and connecting to my AT-230.

After adding the line isolator, the SWR is 5:1 at 7.200mhz,

My rig is also now grounded, electrically, to my house's electrical grounding rod, with a 5 ft piece of heavy gauge wire. The AT-230 is also grounded, with a strap connecting the tuner directly to my TS520. The tuner is connected to the 520 and the 520 is connected to the ground rod.

My house is surrounded, basically, by the power company's high voltage wires. The furthest away I could get the dipole from these HV wires is about 15 feet, maybe. I can't get any further away from the power company's lines than that. I haven't heard any noise on the 520 from those power lines, but I don't know if they might be an issue as well.

I just wanted to get that thrown out there for you to chew on, while I get a voltmeter to test the rig.

The tuner will not tune the antenna on 3.5 mhz, 7mhz or 14 mhz, but it tunes on 21, 28 and 29 mhz. When I try to tune the antenna on 7 mhz (40 meters), I get an electrical arcing noise from the 520. I also noticed that if I calibrate the tuner for too long, to check my antenna's SWR, it will blow the fuse in the TS520. Maybe that's normal, but I am not sure so I thought I would mention it.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

No reason to worry about 5:1 swr until we know what kind of antenna configuration and what freq he is trying to load it on. May be perfectly understandable. Ever see the SWR loading a typical G5RV on 15 or 17 meters?

My guess is with all the RF in the shack may be using end fed antenna? May be using an OCF dipole but I have used them and no problems with RF in shack but I feed with 4:1 current balun at the offset feed point.

All this is just speculation until we know what he is using.

After he gets rig to load properly into 50 ohm dummy load we can all jump in and help resolve the antenna and tuner issues that may exist.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

5 : 1 SWR ?

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Your very first goal is to be able to load the rig into a dummy load on all bands. Worry about using a tuner to load into a multi-band antenna after you are certain you can load "normally" in to the dummy load.

If you can load the rig successfully into dummy load with the tuner in the Bypass Mode (just using the tuner for the wattmeter/SWR meter function) then nothing is wrong with your Pi-Network in the rig unless you are at extreme ends of the Plate Load cap or the Plate Tune cap position doesnt align relatively close to the white panel marking for the band you are loading on.

If you end up having the Plate Load or Plate tune caps at odd positions to attain your 80 to 100 watts into the dummy load you may have bad fixed padder caps.

What would be "normal" is approx 90 to 100 watts into 50 ohm dummy load on all bands with exception of 10 meters (80 watts) at approx 200ma plate current and you should see very close to 1:1 SWR into your dummy load.

If you can do this then time to discuss the antenna and the tuner issues.

Again, your first effort should be to make sure the rig can load normally into a dummy load. This proves your dummy load is good, your interconnecting coax jumpers are good, and the rig is good.

If you cannot do this then no reason to attempt to use the tuner to load in to a multi-band antenna of any type.

The tuner is taking the impedance that the antenna presents at the end of whatever kind of feed line you are using and converting it to an impedance that your rigs Pi-network can match. A multiband antenna can present a wide range of impedances (combination of resistance and reactive) to your rig. The rig cannot match very high impedances (thousands of ohms) that a multiband antenna can present. If you have very high impedance at the end of the feed line in the shack then RF can be a problem in the shack. End fed can present several thousand ohms which means very high RF voltage at the input to the tuner. Sometimes need to install counter poise to resolve this situation.

Describe again what the antenna configuration is. Is this a OCF dipole or a 135 foot flat top fed with 300 ohm ladder line or open wire feeders or a random length end fed ??

It could be that the Tuner has an issue?

So tell us first if you can load rig normally into the dummy load? If so, then describe the complete antenna configuration.

Having resting plate current changing has nothing to do with your antenna or your tuner. You can unscrew your coax connector off back of rig and set resting plate current. Fix that first.

Terry

Installing an 'ugly balun' and getting rid of that stray RF really helped, but it still seems there is something mechanically wrong with the 520. I think that not being able to tune it properly is hurting my AT-230's ability to successfully tune my antenna. I noticed that on 10 and 15 the tuner works fine, but when I get to 20 or 40 it won't match at all. I also still need to ground the radio itself, I have the rig plugged into a standard wall outlet, but in my house, the wall outlets are not grounded (older home), maybe it'll help a little to get the rig properly grounded.

I wish I had the cash to have a professional look at it and realign everything for me. Either way, I'll work on testing those issues that were mentioned by Terry and see where that takes me.

Subject: [TS-520_820_530_830] RE: New Ham, Tuning issues

Hey Terry and everyone:

Sorry this took me so long, I was waiting on parts for my antenna and my AT-230 to arrive in the mail.

I tuned my TS-520 into a dummy load, using the AT-230 as a wattmeter and SWR meter. This is what I observed.

80 meters: Load just about fully meshed, CAR value: 5, 210 ma, 100 watts
40 meters: Load fully meshed, CAR value: 2.75, 210 ma, 80 watts
20 meters: Load 3/4 to meshed, CAR value: 5, 220 ma, 60 watts
15 meters: CAR value: 2.75, 210 ma, 80 watts
10 meters: Load 1/2, CAR value: 4, 210 ma, 80 watts.

I tuned into the center of the band, for voice, on each band.

I noticed that in general, when I keyed the 520 up, the needle for ma would sit at about 240 or 250 ma and then slowly drop off to 210ma on average. I also noticed I had to readjust the bias control for 60ma when I began this whole thing. It was correct the other day, but changed for some reason.

I got all of the stray RF in my shack under control and I checked my antenna and got it to about 5:1 SWR with a nice torroid on it to choke the stray RF. I got a 59 signal report from SW Washington (I am in SW Idaho). I noticed that my tuner won't match the antenna at all on 40 meters or 20 meters, but will match on 15 and 10. I don't know if that is because of an issue with the radio, or the tuner itself, but it was an observation. I get a better SWR on 40 when I am using my antenna without the tuner. In fact, the ham in Washington couldn't hear me at all when I was passing through the tuner, but gave me the 59 without the tuner.

I opened the radio and visually inspected the components you, Terry, suggested. Nothing looks burned, the coils are still shiny and bright and none of the caps looked like they popped, everything, visually, looks clean.

What should I do now?

I was referring to checking and replacing the padder caps and the other items you described the other day. Brain was helping me tune my TS-520 and the discussion was about complications with that. You mentioned in a couple of previous posts that you were talking about a TS-830. I was concerned there was some confusion about what model of Kenwood was experiencing the issues described in this thread. If they all work the same, I'll get those padder caps tested and look at the other items referred to in your previous post.

I hope that's not more confusing, hehe. Brian knows better than I do and was able to explain the problems better than I could.

--- In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

I am exactly sure what you are asking. If you are asking about how to load a TS520 that has no Tune Ip indication to get that initial plate current dip and is it different than a TS-830 then answer is no difference other than limiting the plate current to 200ma.

Some people with lots of experience load in CW mode. Some do this as they have a good understanding of what is going on and the pre-cautions using this method.

Others do it because the Tune position of their rig quit years ago and too lazy to fix it or dont know how to fix it.

I typically do not teach new folks to load in CW.

However if your rigs Tune position is out and you cannot get that initial plate current dip then you can do it by reducing the Car Level pot to minimum and with meter in Ip position Flip to Send and slowly bring the Car Level up to something under 100ma. Have to be careful because Ip can jump very high pretty quickly with very little more opening of the pot.

When you get say around 80ma to 100ma then adjust the plate Tune capacitor for a dip or minimum in plate current and then unkey the rig. Now ready to use the RF relative power

position of the panel meter or your external wattmeter to start coupling load. Flip to Send and alternately adjust Plate Load and Plate Tune controls for max relative power on your RF meter position or approx 100 watts output on your wattmeter. Unkey the rig.

Watching the Ip meter flip to send again and if you are reasonably close to 200ma Ip you are done and ready to operate CW or SSB.

WIth a good Tune position I recommend you follow the instructions in your TS520 manual. Only confusing step is peaking the Drive which says to adjust for maximum meter deflection and everyone and I mean everyone asks "what maximum"? The ALC black box maximum or the meter full scale maximum. As I think I told you black box is meaningless at this step but OK to just peak Drive control at max range on it.

After you get that initial plate current dip in Tune mode then all the Kenwood instruction manuals direct you to load by alternately adjusting :Load and Tune controls for max RF relative power. If you have an external wattmeter leave meter in Ip and load for approx 100 watts out without exceeding 200ma.

For those you may need a RF probe, Hendricks QRP Kits offers the "N2CX Accuprobe Plus" kit for $40. Apparently, this is a redesign of an earlier RF probe that Joe Everhart N2CX designed for the NORTEX QRP club. From the specs listed on the website, it appears that it would be excellent for use with the Kenwood hybrids.

http://www.qrpkits.com/accuprobe.html

I noted this in the "Kit-Building" column of the October 2013 issue of CQ that arrived yesterday.

45016. Re: [TS-520_820_530_830] RE: RE: RE: New Ham, Tuning issues

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-03 12:11:02 UTC
From: Bob Lazarow
Topic: 44440 Message: 45016

On a very basic level, what about the coax and connectors? Is this a store assembled set-up, or home made? What type of coax is it? Have you tested for coax assembly shorts or continuity?

I ask because in your discussion below I didn't see any discussion, unless it was in an earlier post that I missed. And Terry is 100% spot on (he usually is) :forget about the antenna until every thing works properly into a known good dummy load straight from the rig. There are too many variables now.

Good luck

Bob/WA2JAJ

Date: 2013-10-03 12:28:27 UTC
From: Mike
Topic: 44440 Message: 45017

Jason,

Have you tried to trim your dipole ends a small amount at a time for the lowest SWR? When you trim the ends, don't cut the excess wire at the ends, simply shorten the ends by pulling the wire farther through the end insulators and folding the excess wire back along the ends a little at a time. Start with an inch or two on both ends, checking the SWR meter. Each time you trim the length of both side the antenna must be put back up to its intended height above ground before checking the SWR. You will notice the SWR becoming less as you trim, shorten the overall length of both ends by pulling the end wire through the end insulators and twist/wrap the excess end wire around and along itself at both ends. At some point during the trimming process you will find the SWR is the lowest it will be. When you achieve that level of SWR, stop trimming and put the antenna back up to its intended height above ground, you're done.

You said your antenna is cut to 32 feet long on each side. If you use the formula, 468 / freq in Mhz, the initial "Ball Park" end to end length of a dipole for 7.200Mhz is 65 feet (468 / 7.200 = 65). Each side will be approximately 32' 6" long(65 / 2 = 32.6). Once you have built the antenna so each side is approximately 32' 6" long, you now begin to "trim" the length of each side as I stated above.

If youuse coax feed line and want to use a balun, use a 1:1 balun, not a 4:1 balun.

The antenna itself must be kept as far away from surrounding objects as possible, especially metal fences, metal roofs, metal rain gutters etc.

Hi Terry,

I didn't see your response before I made mine, sorry about that. I'll bow out and let you continue.

Hi Jason:

You've got a lot of variables going. I would recommend you work on one small thing at a time, building in a logical sequence towards your ultimate goal of getting on the air. If it were me I would do the following:

1. FORGET THE ANTENNA for now.
2. VERIFY THAT YOUR DUMMY LOAD IS WORKING. As I recall, you built this yourself (which is super!) but don't have test gear. The TS-520 and your SWR meter should be enough to check it.
2a. Connect your dummy load to your SWR meter and connect your SWR meter to the radio. If you are using your AT230, use the dummy load position (no tuning).
2b. Pick a frequency and tune up your TS-520 in the tune position only (peak the drive, dip the plate). Don't switch to CW mode and don't do anything with the load. You don't need 100 watts to see if your dummy load is working (we can test it's power handling capacity later...) You should now have a low power RF signal which is adequate for checking your dummy load. (With the radio in TUNE and SEND you should have at least 10w of output)
2c. Use the power setting on your SWR meter to verify that you have at least 5w of power output from the radio. You will probably have more.
2d. Using the low power RF output of your radio calibrate your SWR meter and then read your SWR. It should be 1:1. If it isn't, then you'll need to move on to testing each piece of equipment in your dummy load set up (coax jumpers, SWR meter, dummy load).
2e. Repeat for each band. Assuming 1:1 in each band then you now know you have a working dummy load, 2 working coax jumpers and a working SWR meter. With this you can move on to the next step, building on the knowledge that you have a known good load/test set up to test against.
3. TEST LOADING THE RADIO into your (now tested) dummy load
3a. Route your output to the dummy load as before
3b. Tune (peak drive, dip plate, load to 200ma) your radio as per instructions from the group or your manual
3c. Re-calibrate your SWR meter (necessary due to the change in power). Set to measure SWR
3d. Note the SWR, load control position and watts out for each band (If you see anything other than a 1:1 SWR, stop. Don't leave the radio in send any longer than you need to in order to take good readings). You might also want to give your radio and dummy load a couple minute break between each band.
3e. Report back to the group

From here we would move on through steps of getting reasonable power at expected plate ma / load control positions. This goes back to the original concern about your difficulty loading the radio on certain bands. Note all of this is still without ever connecting your antenna. Only once everything is working normally into the dummy load would it be time to tackle the antenna, knowing that we have a reliable source of RF that won't arc or blow fuses when properly loaded into a reasonable load.

Glad to hear about your grounding. 5' of heavy cable to a ground rod bonded to your utility service ground is great. Recommend you not daisy chain the ground in the shack (connecting device A to device B to ground). Ideally the ground should connect to a ground bar / ground bus and each device connect directly to that. However, this does not matter until EVERYTHING else is working so this could be for addressing someday in the future after you are happily on the air and want to do some tweaking. It should not have any bearing on what you are working through now.

If I have any of that wrong, hopefully someone on the group will correct.

73,
  Brian (K7TKT)

Subject: [TS-520_820_530_830] RE: RE: RE: New Ham, Tuning issues

I am still working on testing those items you pointed out, Terry. I am trying to get a hold of a voltmeter to see what those values are.

As far as my antenna goes, it's a 40 meter center-fed dipole, each leg is cut at 32 feet. The dipole has a center insulator with a line isolator attached. The isolator is what ended my 'RF in the shack' issues. The dipole is mounted in an inverted V formation, with the center insulator hoisted up on a PVC pipe, 17 feet into the air (about as high as I can get it on my property). both ends of the V are mounted about 5 feet off the ground, the angle is greater than 90 degrees. The feedline is 25 feet of RG-213U coming off of my roof and into my house and connecting to my AT-230.

After adding the line isolator, the SWR is 5:1 at 7.200mhz,

My rig is also now grounded, electrically, to my house's electrical grounding rod, with a 5 ft piece of heavy gauge wire. The AT-230 is also grounded, with a strap connecting the tuner directly to my TS520. The tuner is connected to the 520 and the 520 is connected to the ground rod.

My house is surrounded, basically, by the power company's high voltage wires. The furthest away I could get the dipole from these HV wires is about 15 feet, maybe. I can't get any further away from the power company's lines than that. I haven't heard any noise on the 520 from those power lines, but I don't know if they might be an issue as well.

I just wanted to get that thrown out there for you to chew on, while I get a voltmeter to test the rig.

The tuner will not tune the antenna on 3.5 mhz, 7mhz or 14 mhz, but it tunes on 21, 28 and 29 mhz. When I try to tune the antenna on 7 mhz (40 meters), I get an electrical arcing noise from the 520. I also noticed that if I calibrate the tuner for too long, to check my antenna's SWR, it will blow the fuse in the TS520. Maybe that's normal, but I am not sure so I thought I would mention it.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

No reason to worry about 5:1 swr until we know what kind of antenna configuration and what freq he is trying to load it on. May be perfectly understandable. Ever see the SWR loading a typical G5RV on 15 or 17 meters?

My guess is with all the RF in the shack may be using end fed antenna? May be using an OCF dipole but I have used them and no problems with RF in shack but I feed with 4:1 current balun at the offset feed point.

All this is just speculation until we know what he is using.

After he gets rig to load properly into 50 ohm dummy load we can all jump in and help resolve the antenna and tuner issues that may exist.

Terry K9TW

5 : 1 SWR ?

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Your very first goal is to be able to load the rig into a dummy load on all bands. Worry about using a tuner to load into a multi-band antenna after you are certain you can load "normally" in to the dummy load.

If you can load the rig successfully into dummy load with the tuner in the Bypass Mode (just using the tuner for the wattmeter/SWR meter function) then nothing is wrong with your Pi-Network in the rig unless you are at extreme ends of the Plate Load cap or the Plate Tune cap position doesnt align relatively close to the white panel marking for the band you are loading on.

If you end up having the Plate Load or Plate tune caps at odd positions to attain your 80 to 100 watts into the dummy load you may have bad fixed padder caps.

What would be "normal" is approx 90 to 100 watts into 50 ohm dummy load on all bands with exception of 10 meters (80 watts) at approx 200ma plate current and you should see very close to 1:1 SWR into your dummy load.

If you can do this then time to discuss the antenna and the tuner issues.

Again, your first effort should be to make sure the rig can load normally into a dummy load. This proves your dummy load is good, your interconnecting coax jumpers are good, and the rig is good.

If you cannot do this then no reason to attempt to use the tuner to load in to a multi-band antenna of any type.

The tuner is taking the impedance that the antenna presents at the end of whatever kind of feed line you are using and converting it to an impedance that your rigs Pi-network can match. A multiband antenna can present a wide range of impedances (combination of resistance and reactive) to your rig. The rig cannot match very high impedances (thousands of ohms) that a multiband antenna can present. If you have very high impedance at the end of the feed line in the shack then RF can be a problem in the shack. End fed can present several thousand ohms which means very high RF voltage at the input to the tuner. Sometimes need to install counter poise to resolve this situation.

Describe again what the antenna configuration is. Is this a OCF dipole or a 135 foot flat top fed with 300 ohm ladder line or open wire feeders or a random length end fed ??

It could be that the Tuner has an issue?

So tell us first if you can load rig normally into the dummy load? If so, then describe the complete antenna configuration.

Having resting plate current changing has nothing to do with your antenna or your tuner. You can unscrew your coax connector off back of rig and set resting plate current. Fix that first.

Installing an 'ugly balun' and getting rid of that stray RF really helped, but it still seems there is something mechanically wrong with the 520. I think that not being able to tune it properly is hurting my AT-230's ability to successfully tune my antenna. I noticed that on 10 and 15 the tuner works fine, but when I get to 20 or 40 it won't match at all. I also still need to ground the radio itself, I have the rig plugged into a standard wall outlet, but in my house, the wall outlets are not grounded (older home), maybe it'll help a little to get the rig properly grounded.

I wish I had the cash to have a professional look at it and realign everything for me. Either way, I'll work on testing those issues that were mentioned by Terry and see where that takes me.

Subject: [TS-520_820_530_830] RE: New Ham, Tuning issues

Hey Terry and everyone:

Sorry this took me so long, I was waiting on parts for my antenna and my AT-230 to arrive in the mail.

I tuned my TS-520 into a dummy load, using the AT-230 as a wattmeter and SWR meter. This is what I observed.

80 meters: Load just about fully meshed, CAR value: 5, 210 ma, 100 watts
40 meters: Load fully meshed, CAR value: 2.75, 210 ma, 80 watts
20 meters: Load 3/4 to meshed, CAR value: 5, 220 ma, 60 watts
15 meters: CAR value: 2.75, 210 ma, 80 watts
10 meters: Load 1/2, CAR value: 4, 210 ma, 80 watts.

I tuned into the center of the band, for voice, on each band.

I noticed that in general, when I keyed the 520 up, the needle for ma would sit at about 240 or 250 ma and then slowly drop off to 210ma on average. I also noticed I had to readjust the bias control for 60ma when I began this whole thing. It was correct the other day, but changed for some reason.

I got all of the stray RF in my shack under control and I checked my antenna and got it to about 5:1 SWR with a nice torroid on it to choke the stray RF. I got a 59 signal report from SW Washington (I am in SW Idaho). I noticed that my tuner won't match the antenna at all on 40 meters or 20 meters, but will match on 15 and 10. I don't know if that is because of an issue with the radio, or the tuner itself, but it was an observation. I get a better SWR on 40 when I am using my antenna without the tuner. In fact, the ham in Washington couldn't hear me at all when I was passing through the tuner, but gave me the 59 without the tuner.

I opened the radio and visually inspected the components you, Terry, suggested. Nothing looks burned, the coils are still shiny and bright and none of the caps looked like they popped, everything, visually, looks clean.

What should I do now?

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

When I said that I was "exactly sure" I meant to type that I was "NOT EXACTLY" sure what you were asking. Should have waited for your response.. Sorry!

Anyway, with a key plugged in you don't get any output with the alternate procedure without closing the key for obvious reasons. I've been so used to how the radio responded when I switched over from tune to CW with a key connected that I ended up thinking the key was necessary. My bad. For me the long procedure from the manual works fine since I always have the key connected and normally have the radio in VOX mode (to save wear on the send switch) but I have a better understanding now. Thank you. I will also study the diagram to try to better understand the relationship between the load capacitor and antenna load.
>>>>>>>>>>>
>>>>>>>>>>>
>>>>>>>>>>>This will also help Jason since I took him through the long procedure from the manual that uses a key. He can just unplug his keyer and will be able to move from tuning

to loading once he has the drive and plate a resonance (peaked and dipped) without all of the additional gyrations.
>>>>>>>>>>>>
>>>>>>>>>>>>
>>>>>>>>>>>>Questions: This still leaves Jason's TS-520's issue with load. Even though I was using the long procedure with the key, I think the results are still accurate. He is getting a maximum output of 70w at 200ma with the load at min (fully CCW) and reducing the load capacitance (increasing the load/turning load CW) actually reduces his output. This isn't normal, right? I can simulate this on my TS-830 but it pains me. If I intentionally turn the load up too much, output falls off as I increase the load. So...I think in Jason's TS520 it is as if even at maximum capacitance (minimum load) he doesn't have enough to balance against the 50 ohm dummy load---resonance is off the minimum end of the load. Does that sound like a reasonable conclusion? Is the next step for us to try the tune up procedure on all bands and report back (your 10m suggestion from before) or is there something else that we should check first?

>>>>>>>>>>>>
>>>>>>>>>>>>After you make that initial plate current dip in Tune mode you do not need to do any more dip and load procedure. Only reason you do this initial dip is to get the tank circuit adjusted close to resonance so when you go to CW mode and apply full screen grid voltage to the finals you dont peg the IP meter if the tank is tuned off resonance. This could damage your finals if left keyed too long at this high Ip level.
>>>>>>>>>>>>
>>>>>>>>>>>>
>>>>>>>>>>>>Read the very last note in the TS-830 loading procedure. It tells you after they have taught you dip and load you dont have to use it as it isnt best or easiest way to load a Class AB1 linear amp!

Mike...ditto on my response. Was typing and didn't see yours. Still think it would be wise to make sure everything is working right in the shack before moving on to the antenna but I will yield to you folks with more experience.

73,
  Brian (K7TKT)

Hi Terry,

I didn't see your response before I made mine, sorry about that.
I'll bow out and let you continue.

>
>
>Should never get an electrical arcing noise in PA cage when loading a 40 meter dipole on 40 meters. Most common reason for arcing is Plate load cap arcing over but you almost need to have an open at the SO-239 to get high enough RF voltage.
>
>
>Just remove this Tuner and use the RF detector position and load your radio exactly as the manual says to do. Move up to 7.297mhz and load there. After you get the initial dip in Tune mode then go to CW mode and put meter in RF and load by alternately adjusting the Plate Load and Tune controls for maximum relative power indication on your meter. Place meter switch back to Ip and make sure not exceeding approx 200 ma. The rig is loaded.
>
>
>If you cannot load this radio without a Tuner into a dummy load on 40 meters or into a 40 meter dipole there is no point in adding a Tuner into the equation. If rig arcs over loading into dummy load and or antenna check your coax jumpers. May have a bad jumper. Takes a very high VSWR to produce very high RF voltage across the Plate Load cap. Highest would be if you have an open. If you have an open the rig will try to load into it and not easy for you to recognize that by looking at RF or IP meter position unless you have experience.

>
>
>As far as my antenna goes, it's a 40 meter center-fed dipole, each leg is cut at 32 feet.

The dipole has a center insulator with a line isolator attached. The isolator is what ended my 'RF in the shack' issues. The dipole is mounted in an inverted V formation, with the center insulator hoisted up on a PVC pipe, 17 feet into the air (about as high as I can get it on my property). both ends of the V are mounted about 5 feet off the ground, the angle is greater than 90 degrees. The feedline is 25 feet of RG-213U coming off of my roof and into my house and connecting to my AT-230.

>After adding the line isolator, the SWR is 5:1 at 7.200mhz,
>
>
>My rig is also now grounded, electrically, to my house's electrical grounding rod, with a 5 ft piece of heavy gauge wire. The AT-230 is also grounded, with a strap connecting the tuner directly to my TS520. The tuner is connected to the 520 and the 520 is connected to the ground rod.
>
>
>My house is surrounded, basically, by the power company's high voltage wires. The furthest away I could get the dipole from these HV wires is about 15 feet, maybe. I can't get any further away from the power company's lines than that. I haven't heard any noise on the 520 from those power lines, but I don't know if they might be an issue as well.
>
>
>I just wanted to get that thrown out there for you to chew on, while I get a voltmeter to test the rig.
>
>
>The tuner will not tune the antenna on 3.5 mhz, 7mhz or 14 mhz, but it tunes on 21, 28 and 29 mhz. When I try to tune the antenna on 7 mhz (40 meters), I get an electrical arcing noise from the 520. I also noticed that if I calibrate the tuner for too long, to check my antenna's SWR, it will blow the fuse in the TS520. Maybe that's normal, but I am not sure so I thought I would mention it.

>
>
>The tuner is taking the impedance that the antenna presents at the end of whatever kind of feed line you are using and converting it to an impedance that your rigs Pi-network can match. A multiband antenna can present a wide range of impedances (combination of

resistance and reactive) to your rig. The rig cannot match very high impedances (thousands of ohms) that a multiband antenna can present. If you have very high impedance at the end of the feed line in the shack then RF can be a problem in the shack. End fed can present several thousand ohms which means very high RF voltage at the input to the tuner. Sometimes need to install counter poise to resolve this situation.

>Installing an 'ugly balun' and getting rid of that stray RF really helped, but it still seems there is something mechanically wrong with the 520. I think that not being able to tune it properly is hurting my AT-230's ability to successfully tune my antenna. I noticed that on 10 and 15 the tuner works fine, but when I get to 20 or 40 it won't match at all. I also still need to ground the radio itself, I have the rig plugged into a standard wall outlet, but in my house, the wall outlets are not grounded (older home), maybe it'll help a little to get the rig properly grounded.

>>>>>>>>>>>>>Ah ha. I am a CW op so I always have had a key plugged in (but no mic). Anyway, with a key plugged in you don't get any output with the alternate procedure without closing the key for obvious reasons. I've been so used to how the radio responded when I switched over from tune to CW with a key connected that I ended up thinking the key was necessary. My bad. For me the long procedure from the manual works fine since I always have the key connected and normally have the radio in VOX mode (to save wear on the send switch) but I have a better understanding now. Thank you. I will also study the diagram to try to better understand the relationship between the load capacitor and antenna load.
>>>>>>>>>>>>>
>>>>>>>>>>>>>
>>>>>>>>>>>>>This will also help Jason since I took him through the long procedure from the manual that uses a key. He can just unplug his keyer and will be able to move from tuning to loading once he has the drive and plate a resonance (peaked and dipped) without all of the additional gyrations.
>>>>>>>>>>>>>
>>>>>>>>>>>>>
>>>>>>>>>>>>>Questions: This still leaves Jason's TS-520's issue with load. Even though I was using the long procedure with the key, I think the results are still accurate. He is getting a maximum output of 70w at 200ma with the load at min (fully CCW) and reducing the load capacitance (increasing the load/turning load CW) actually reduces his output. This

isn't normal, right? I can simulate this on my TS-830 but it pains me. If I intentionally turn the load up too much, output falls off as I increase the load. So...I think in Jason's TS520 it is as if even at maximum capacitance (minimum load) he doesn't have enough to balance against the 50 ohm dummy load---resonance is off the minimum end of the load. Does that sound like a reasonable conclusion? Is the next step for us to try the tune up procedure on all bands and report back (your 10m suggestion from before) or is there something else that we should check first?

>>>>>>>>>>>>>
>>>>>>>>>>>>>
>>>>>>>>>>>>>>At this point with plates fully meshed you have maximum capacitance and lowest capacitive reactance so the RF current in the tank is going to like to flow thru the plate load cap and not thru the dummy load. Sometime look at formula for Xc and you will see it is an inverse relationship. It will help you understand what I am telling you.
>>>>>>>>>>>>>
>>>>>>>>>>>>>
>>>>>>>>>>>>>>OK --You havent started tightening up the coupling yet and shifting the tank circuit RF circ current to the dummy load resistance. Each time you open the plates of the Load cap a little more you are decreasing the capacitance and increasing the capacitive reactance XC. This allows more current to flow in the dummy load resistor or the antenna.
>>>>>>>>>>>>>
>>>>>>>>>>>>>
>>>>>>>>>>>>>>When you get to full load you will have opened the Plate Load capactor to the point that the XC is approx equal to the dummy load or antenna resistance. At this point you will have used half of the stored energy in the tank and there will be equal RF current flowing thru the Plate load capacitor and the dummy load resistor. At that point with 100 watts output power there will be approx 1.4 RF amps flowing thru the Plate load cap and 1.4

RF amps flowing thru the 50 ohm dummy load.
>>>>>>>>>>>>>>
>>>>>>>>>>>>>>
>>>>>>>>>>>>>>>This is all simple ohms law for parallel resistors, but not too many folks really understand what they are doing or how it works or have just never given it any serious thought.
>>>>>>>>>>>>>>
>>>>>>>>>>>>>>
>>>>>>>>>>>>>>
>>>>>>>>>>>>>>>After you make that initial plate current dip in Tune mode you do not need to do any more dip and load procedure. Only reason you do this initial dip is to get the tank circuit adjusted close to resonance so when you go to CW mode and apply full screen grid voltage to the finals you dont peg the IP meter if the tank is tuned off resonance. This could damage your finals if left keyed too long at this high Ip level.
>>>>>>>>>>>>>>
>>>>>>>>>>>>>>
>>>>>>>>>>>>>>>Read the very last note in the TS-830 loading procedure. It tells you after they have taught you dip and load you dont have to use it as it isnt best or easiest way to load a Class AB1 linear amp!

From: <wagstw46@...>
Topic: 44440 Message: 45021

I have suggested more than once:
1. Fix the resting plate current issue
2. Confirm can load on all bands into dummy load.
3. Make sure all coax jumpers being used are not open or shorted or have a high resistance connection.
4. Then try to load into 40 meter coax fed dipole with Tuner in Bypass (using same jumpers).
5. I suspect antenna as currently assembled is resonant outside top end of 40 meter band. Appears he has cut it short for 7.200 mhz. A very quick check would be to load just below 7.300 to see if SWR is lower than 5:1 there..
6. Another very quick check is hang alligator clip leads off the copper flat top wire at each end insulator and just let them hang down. Then go down to around 7.150 and test load. See if adding 10- 12 inches moves resonance down and lowers SWR.
7. I am concerned about this Toroid. What is it and where installed? Is it a 1:1 choke at the input to the Tuner? Is it a 4:1 balun at input of Tuner? I sure hope not.
8. All this RF in shack with a coax fed 1/2 wave dipole is not norm. Perhaps he has one leg longer than other or there is a lot of interaction between nearby objects causing unbalance?

He is waiting on test equipment to measure operating bias voltage. Can just go ahead and Deoxit the bias voltage pot and clean and reset it now and see if that fixes is resting plate current issue.

If it does in about 10 minutes with this Tuner out of the equation he can find out where the dipole is resonant at and add or subtract wire as needed to put it where he wants it. Again if he plans to use Tuner all the time as so many new folks seem to think is necessary then just cut it for 7.150 and use Tuner to present 1:1 wherever he wants to operate. I dont understand why anyone wants to put two impedance matching devices in series to feed a resonant dipole and add 3 more mystery knobs to twiddle everytime you move 5 khz, but I see it all the time. I dont have the energy to try to educate anyone on this. Only time you need a "transmatch" is when you want to multi-band an antenna. Then better to use as much flat top as you can and feed with 300 ohm ladder line (not coax) and use balanced tuner. For coax fed and multiband then can look at G5RV or OCF dipoles. . .

There is plenty of help for him here when it comes to Tuners and Antennas. I will back off at this point and if he needs help troubleshooting the radio I will be available. I am much more comfortable in that role.

First thing. It is ok to place a 1:1 choke in line at the center insulator but can tell you hams ran resonant dipoles for many many years with the coax directly feeding each leg of the dipole and never knew there was any current on outside of the shield and never caused any RF problems in the shack. At this point dont worry about that.

467/7.2mhz = 64 foot 10 inches or 32 foot 5 inches each leg.

Your 64 foot = 467/64 = 7.297mhz. Your antenna is too short for 7.2 mhz assuming that is where you want it to be resonant at. You can easily add about 6 inches to each end and just let it hang done at the end insulator eye. No need to remove and add wire at this point.

Was 7.200 your objective? Center of phone band? Center of the allocation? If you insist on using Tuner and having 1:1 across the band then just cut it for 7.150mhz.

You can easily determine whether you need to add or remove wire by loading into it on either side of where you now have this "low or best" SWR of 5:1 and see which direction causes lower SWR. .

If the SWR gets lower as you move up in frequency you know antenna is too short and you need to add wire to each leg. If SWR gets better as you move down in frequency then you know antenna is too long and you need to remove wire on each leg.

Make sure you check my math.

Using a 40 meter antenna on 80 meters is not going to be very efficient.

Should never get an electrical arcing noise in PA cage when loading a 40 meter dipole on 40 meters. Most common reason for arcing is Plate load cap arcing over but you almost need to have an open at the SO-239 to get high enough RF voltage.

Just remove this Tuner and use the RF detector position and load your radio exactly as the manual says to do. Move up to 7.297mhz and load there. After you get the initial dip in Tune mode then go to CW mode and put meter in RF and load by alternately adjusting the Plate Load and Tune controls for maximum relative power indication on your meter. Place meter switch back to Ip and make sure not exceeding approx 200 ma. The rig is loaded.

If you cannot load this radio without a Tuner into a dummy load on 40 meters or into a 40 meter dipole there is no point in adding a Tuner into the equation. If rig arcs over loading into dummy load and or antenna check your coax jumpers. May have a bad jumper. Takes a very high VSWR to produce very high RF voltage across the Plate Load cap. Highest would be if you have an open. If you have an open the rig will try to load into it and not easy for you to recognize that by looking at RF or IP meter position unless you have experience.

When you can load normally on all bands into the dummy load and into the 40 meter dipole on 40 meters then time to see if you have a good Tuner.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

I am still working on testing those items you pointed out, Terry. I am trying to get a hold of a voltmeter to see what those values are.

As far as my antenna goes, it's a 40 meter center-fed dipole, each leg is cut at 32 feet. The dipole has a center insulator with a line isolator attached. The isolator is what ended my 'RF in the shack' issues. The dipole is mounted in an inverted V formation, with the center insulator hoisted up on a PVC pipe, 17 feet into the air (about as high as I can get it on my property). both ends of the V are mounted about 5 feet off the ground, the angle is greater than 90 degrees. The feedline is 25 feet of RG-213U coming off of my roof and into my house and connecting to my AT-230.

After adding the line isolator, the SWR is 5:1 at 7.200mhz,

My rig is also now grounded, electrically, to my house's electrical grounding rod, with a 5 ft piece of heavy gauge wire. The AT-230 is also grounded, with a strap connecting the tuner directly to my TS520. The tuner is connected to the 520 and the 520 is connected to the ground rod.

My house is surrounded, basically, by the power company's high voltage wires. The furthest away I could get the dipole from these HV wires is about 15 feet, maybe. I can't get any further away from the power company's lines than that. I haven't heard any noise on the 520 from those power lines, but I don't know if they might be an issue as well.

I just wanted to get that thrown out there for you to chew on, while I get a voltmeter to test the rig.

The tuner will not tune the antenna on 3.5 mhz, 7mhz or 14 mhz, but it tunes on 21, 28 and 29 mhz. When I try to tune the antenna on 7 mhz (40 meters), I get an electrical arcing noise from the 520. I also noticed that if I calibrate the tuner for too long, to check my antenna's SWR, it will blow the fuse in the TS520. Maybe that's normal, but I am not sure so I thought I would mention it.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

No reason to worry about 5:1 swr until we know what kind of antenna configuration and what freq he is trying to load it on. May be perfectly understandable. Ever see the SWR loading a typical G5RV on 15 or 17 meters?

My guess is with all the RF in the shack may be using end fed antenna? May be using an OCF dipole but I have used them and no problems with RF in shack but I feed with 4:1 current balun at the offset feed point.

All this is just speculation until we know what he is using.

After he gets rig to load properly into 50 ohm dummy load we can all jump in and help resolve the antenna and tuner issues that may exist.

5 : 1 SWR ?

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Your very first goal is to be able to load the rig into a dummy load on all bands. Worry about using a tuner to load into a multi-band antenna after you are certain you can load "normally" in to the dummy load.

If you can load the rig successfully into dummy load with the tuner in the Bypass Mode (just using the tuner for the wattmeter/SWR meter function) then nothing is wrong with your Pi-Network in the rig unless you are at extreme ends of the Plate Load cap or the Plate Tune cap position doesnt align relatively close to the white panel marking for the band you are loading on.

If you end up having the Plate Load or Plate tune caps at odd positions to attain your 80 to 100 watts into the dummy load you may have bad fixed padder caps.

What would be "normal" is approx 90 to 100 watts into 50 ohm dummy load on all bands with exception of 10 meters (80 watts) at approx 200ma plate current and you should see very close to 1:1 SWR into your dummy load.

If you can do this then time to discuss the antenna and the tuner issues.

Again, your first effort should be to make sure the rig can load normally into a dummy load. This proves your dummy load is good, your interconnecting coax jumpers are good, and the rig is good.

If you cannot do this then no reason to attempt to use the tuner to load in to a multi-band antenna of any type.

The tuner is taking the impedance that the antenna presents at the end of whatever kind of feed line you are using and converting it to an impedance that your rigs Pi-network can match. A multiband antenna can present a wide range of impedances (combination of resistance and reactive) to your rig. The rig cannot match very high impedances (thousands of ohms) that a multiband antenna can present. If you have very high impedance at the end of the feed line in the shack then RF can be a problem in the shack. End fed can present several thousand ohms which means very high RF voltage at the input to the tuner. Sometimes need to install counter poise to resolve this situation.

Describe again what the antenna configuration is. Is this a OCF dipole or a 135 foot flat top fed with 300 ohm ladder line or open wire feeders or a random length end fed ??

It could be that the Tuner has an issue?

So tell us first if you can load rig normally into the dummy load? If so, then describe the complete antenna configuration.

Having resting plate current changing has nothing to do with your antenna or your tuner. You can unscrew your coax connector off back of rig and set resting plate current. Fix that first.

Installing an 'ugly balun' and getting rid of that stray RF really helped, but it still seems there is something mechanically wrong with the 520. I think that not being able to tune it properly is hurting my AT-230's ability to successfully tune my antenna. I noticed that on 10 and 15 the tuner works fine, but when I get to 20 or 40 it won't match at all. I also still need to ground the radio itself, I have the rig plugged into a standard wall outlet, but in my house, the wall outlets are not grounded (older home), maybe it'll help a little to get the rig properly grounded.

I wish I had the cash to have a professional look at it and realign everything for me. Either way, I'll work on testing those issues that were mentioned by Terry and see where that takes me.

Subject: [TS-520_820_530_830] RE: New Ham, Tuning issues

Hey Terry and everyone:

Sorry this took me so long, I was waiting on parts for my antenna and my AT-230 to arrive in the mail.

I tuned my TS-520 into a dummy load, using the AT-230 as a wattmeter and SWR meter. This is what I observed.

80 meters: Load just about fully meshed, CAR value: 5, 210 ma, 100 watts

40 meters: Load fully meshed, CAR value: 2.75, 210 ma, 80 watts

I forgot to mention to set the forward sensitivity on your SWR bridge you dont need to use full power. If you are blowing the rigs primary fuse trying to set the SWR bridge sensitivity pot then you probably have rig key down too long in an off resonant state.

Before setting the SWR bridge follow normal loading by peaking your ALC drive, placing rig in Tune mode and perform your Plate current dip. Leave in Tune and adjust your SWR meter sensitivity. As someone mentioned you do not need full power to check SWR of your antenna.

You may want to consider buying a Drake W4 wattmeter and just use the nomograph to read SWR from Forward and Reflected power or buy a MFJ Cross Needle wattmeter. Can then use either meter as a Loading aid, a wattmeter, and SWR meter with no adjustment of a forward power sensitivity pot required. Very easy to use.

Of course the fuse blowing can be due to other problems but try dipping plate current in Tune mode then set SWR bridge in Tune mode and measure SWR in Tune mode.

Again, your first effort should be to make sure the rig can load normally into a dummy load. This proves your dummy load is good, your interconnecting coax jumpers are good, and the rig is good.

If you cannot do this then no reason to attempt to use the tuner to load in to a multi-band antenna of any type.

The tuner is taking the impedance that the antenna presents at the end of whatever kind of feed line you are using and converting it to an impedance that your rigs Pi-network can match. A multiband antenna can present a wide range of impedances (combination of resistance and reactive) to your rig. The rig cannot match very high impedances (thousands of ohms) that a multiband antenna can present. If you have very high impedance at the end of the feed line in the shack then RF can be a problem in the shack. End fed can present several thousand ohms which means very high RF voltage at the input to the tuner. Sometimes need to install counter poise to resolve this situation.

Describe again what the antenna configuration is. Is this a OCF dipole or a 135 foot flat top fed with 300 ohm ladder line or open wire feeders or a random length end fed ??

It could be that the Tuner has an issue?

So tell us first if you can load rig normally into the dummy load? If so, then describe the complete antenna configuration.

Having resting plate current changing has nothing to do with your antenna or your tuner. You can unscrew your coax connector off back of rig and set resting plate current. Fix that first.

One final final final comment. I promise!

If you are going to use a 40 meter coax fed dipole as a multi-band antenna why do you care what the SWR is? The SWR is going to be all over the place depending on harmonic relationship of band your are loading on. As long at your Tuner can handle the impedance that is presented there is no reason to ever measure the SWR. You dont measure SWR on a multiband antenna fed with 300 or 450 or 600 ohm feeders. Impedance on a classic center fed Zepp with 300 ohm feedline can range from 100 ohms to 5000 ohms. Common to see 1200 ohms which would be 1200/50 = 24:1 SWR. No concern about this as the 300 ohm line has very low loss. As long as the Tuner can take that 1200 ohms and transform it to approx 50 ohms for the transmitter this high SWR is of no significance.

Same for your coax fed multiband dipole. As long as the Tuner can take the high impedance presented and transform it to close to 50 ohms for you TS-520 the SWR is meaningless other than one significant difference and that is the coax losses which you have chosen to accept by using this method of feed.

Not a very good idea to feed a multiband antenna with coax except in special cases like G5RV or OCF dipoles. It will work but not best efficiency. It is convenient from getting feed line into the shack. I guess that is why it is used?

If you need help with the rig let me know.

Terry

I forgot to mention to set the forward sensitivity on your SWR bridge you dont need to use full power. If you are blowing the rigs primary fuse trying to set the SWR bridge sensitivity pot then you probably have rig key down too long in an off resonant state.

Before setting the SWR bridge follow normal loading by peaking your ALC drive, placing rig in Tune mode and perform your Plate current dip. Leave in Tune and adjust your SWR meter sensitivity. As someone mentioned you do not need full power to check SWR of your antenna.

You may want to consider buying a Drake W4 wattmeter and just use the nomograph to read SWR from Forward and Reflected power or buy a MFJ Cross Needle wattmeter. Can then use either meter as a Loading aid, a wattmeter, and SWR meter with no adjustment of a forward power sensitivity pot required. Very easy to use.

Of course the fuse blowing can be due to other problems but try dipping plate current in Tune mode then set SWR bridge in Tune mode and measure SWR in Tune mode.

I have suggested more than once:
1. Fix the resting plate current issue
2. Confirm can load on all bands into dummy load.
3. Make sure all coax jumpers being used are not open or shorted or have a high resistance connection.
4. Then try to load into 40 meter coax fed dipole with Tuner in Bypass (using same jumpers).
5. I suspect antenna as currently assembled is resonant outside top end of 40 meter band. Appears he has cut it short for 7.200 mhz. A very quick check would be to load just below 7.300 to see if SWR is lower than 5:1 there..
6. Another very quick check is hang alligator clip leads off the copper flat top wire at each end insulator and just let them hang down. Then go down to around 7.150 and test load. See if adding 10- 12 inches moves resonance down and lowers SWR.
7. I am concerned about this Toroid. What is it and where installed? Is it a 1:1 choke at the input to the Tuner? Is it a 4:1 balun at input of Tuner? I sure hope not.
8. All this RF in shack with a coax fed 1/2 wave dipole is not norm. Perhaps he has one leg longer than other or there is a lot of interaction between nearby objects causing unbalance?

He is waiting on test equipment to measure operating bias voltage. Can just go ahead and Deoxit the bias voltage pot and clean and reset it now and see if that fixes is resting plate current issue.

If it does in about 10 minutes with this Tuner out of the equation he can find out where the dipole is resonant at and add or subtract wire as needed to put it where he wants it. Again if he plans to use Tuner all the time as so many new folks seem to think is necessary then just cut it for 7.150 and use Tuner to present 1:1 wherever he wants to operate. I dont understand why anyone wants to put two impedance matching devices in series to feed a resonant dipole and add 3 more mystery knobs to twiddle everytime you move 5 khz, but I see it all the time. I dont have the energy to try to educate anyone on this. Only time you need a "transmatch" is when you want to multi-band an antenna. Then better to use as much flat top as you can and feed with 300 ohm ladder line (not coax) and use balanced tuner. For coax fed and multiband then can look at G5RV or OCF dipoles. . .

There is plenty of help for him here when it comes to Tuners and Antennas. I will back off at this point and if he needs help troubleshooting the radio I will be available. I am much more comfortable in that role.

First thing. It is ok to place a 1:1 choke in line at the center insulator but can tell you hams ran resonant dipoles for many many years with the coax directly feeding each leg of the dipole and never knew there was any current on outside of the shield and never caused any RF problems in the shack. At this point dont worry about that.

467/7.2mhz = 64 foot 10 inches or 32 foot 5 inches each leg.

Your 64 foot = 467/64 = 7.297mhz. Your antenna is too short for 7.2 mhz assuming that is where you want it to be resonant at. You can easily add about 6 inches to each end and just let it hang done at the end insulator eye. No need to remove and add wire at this point.

Was 7.200 your objective? Center of phone band? Center of the allocation? If you insist on using Tuner and having 1:1 across the band then just cut it for 7.150mhz.

You can easily determine whether you need to add or remove wire by loading into it on either side of where you now have this "low or best" SWR of 5:1 and see which direction causes lower SWR. .

If the SWR gets lower as you move up in frequency you know antenna is too short and you need to add wire to each leg. If SWR gets better as you move down in frequency then you know antenna is too long and you need to remove wire on each leg.

Make sure you check my math.

Using a 40 meter antenna on 80 meters is not going to be very efficient.

Should never get an electrical arcing noise in PA cage when loading a 40 meter dipole on 40 meters. Most common reason for arcing is Plate load cap arcing over but you almost need to have an open at the SO-239 to get high enough RF voltage.

Just remove this Tuner and use the RF detector position and load your radio exactly as the manual says to do. Move up to 7.297mhz and load there. After you get the initial dip in Tune mode then go to CW mode and put meter in RF and load by alternately adjusting the Plate Load and Tune controls for maximum relative power indication on your meter. Place meter switch back to Ip and make sure not exceeding approx 200 ma. The rig is loaded.

If you cannot load this radio without a Tuner into a dummy load on 40 meters or into a 40 meter dipole there is no point in adding a Tuner into the equation. If rig arcs over loading into dummy load and or antenna check your coax jumpers. May have a bad jumper. Takes a very high VSWR to produce very high RF voltage across the Plate Load cap. Highest would be if you have an open. If you have an open the rig will try to load into it and not easy for you to recognize that by looking at RF or IP meter position unless you have experience.

When you can load normally on all bands into the dummy load and into the 40 meter dipole on 40 meters then time to see if you have a good Tuner.

Terry K9TW

I am still working on testing those items you pointed out, Terry. I am trying to get a hold of a voltmeter to see what those values are.

As far as my antenna goes, it's a 40 meter center-fed dipole, each leg is cut at 32 feet. The dipole has a center insulator with a line isolator attached. The isolator is what ended my 'RF in the shack' issues. The dipole is mounted in an inverted V formation, with the center insulator hoisted up on a PVC pipe, 17 feet into the air (about as high as I can get it on my property). both ends of the V are mounted about 5 feet off the ground, the angle is greater than 90 degrees. The feedline is 25 feet of RG-213U coming off of my roof and into my house and connecting to my AT-230.

After adding the line isolator, the SWR is 5:1 at 7.200mhz,

My rig is also now grounded, electrically, to my house's electrical grounding rod, with a 5 ft piece of heavy gauge wire. The AT-230 is also grounded, with a strap connecting the tuner directly to my TS520. The tuner is connected to the 520 and the 520 is connected to the ground rod.

My house is surrounded, basically, by the power company's high voltage wires. The furthest away I could get the dipole from these HV wires is about 15 feet, maybe. I can't get any further away from the power company's lines than that. I haven't heard any noise on the 520 from those power lines, but I don't know if they might be an issue as well.

I just wanted to get that thrown out there for you to chew on, while I get a voltmeter to test the rig.

The tuner will not tune the antenna on 3.5 mhz, 7mhz or 14 mhz, but it tunes on 21, 28 and 29 mhz. When I try to tune the antenna on 7 mhz (40 meters), I get an electrical arcing noise from the 520. I also noticed that if I calibrate the tuner for too long, to check my antenna's SWR, it will blow the fuse in the TS520. Maybe that's normal, but I am not sure so I thought I would mention it.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

No reason to worry about 5:1 swr until we know what kind of antenna configuration and what freq he is trying to load it on. May be perfectly understandable. Ever see the SWR loading a typical G5RV on 15 or 17 meters?

My guess is with all the RF in the shack may be using end fed antenna? May be using an OCF dipole but I have used them and no problems with RF in shack but I feed with 4:1 current balun at the offset feed point.

All this is just speculation until we know what he is using.

After he gets rig to load properly into 50 ohm dummy load we can all jump in and help resolve the antenna and tuner issues that may exist.

5 : 1 SWR ?

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Your very first goal is to be able to load the rig into a dummy load on all bands. Worry about using a tuner to load into a multi-band antenna after you are certain you can load "normally" in to the dummy load.

If you can load the rig successfully into dummy load with the tuner in the Bypass Mode (just using the tuner for the wattmeter/SWR meter function) then nothing is wrong with your Pi-Network in the rig unless you are at extreme ends of the Plate Load cap or the Plate Tune cap position doesnt align relatively close to the white panel marking for the band you are loading on.

If you end up having the Plate Load or Plate tune caps at odd positions to attain your 80 to 100 watts into the dummy load you may have bad fixed padder caps.

What would be "normal" is approx 90 to 100 watts into 50 ohm dummy load on all bands with exception of 10 meters (80 watts) at approx 200ma plate current and you should see very close to 1:1 SWR into your dummy load.

If you can do this then time to discuss the antenna and the tuner issues.

Again, your first effort should be to make sure the rig can load normally into a dummy load. This proves your dummy load is good, your interconnecting coax jumpers are good, and the rig is good.

A good multi band antenna is the G5RV. I fed the G5RV with RG-8x and used a Drake MN-2000 tuner. The exciter was a Drake T4XC transmitter. I've used it with a Heathkit HW-101. Tuning the transmitter into a 50 ohm dummy load first then switching to the tuner, not touching the transmitter controls but adjust only the tuner controls for lowest SWR. Works every time.

There are various models of the G5RV, I used the 102 foot version. Tuning on 80 was a bit tight, less than 30Khz of bandwidth, and I could get the SWR to 1.2:1. On the higher bands it worked very well and tuning the tuner was much easier.

The G5RV can be errected as a horizontal dipole or in an inverted vee fashion. I had mine in the horizontal fashion, I have the real estate needed for the 102 foot version. I do not recommend wrapping the 450 ohm line around a support object such as a tree if you don't have the real estate. The G5RV should put up as high as possible so the 450 ohm line is straight. If you do not have the real estate for 102 foot long version then there's a shorter version you might be able to use. Either way, the G5RV works very well as a multi band antenna.

Mike,

I have to agree fully on the G5RV 102' version as a VERY good multiband antenna. I don't know why they get such a bad name, and for some, they are the only thing that comes close to fitting their lot. I don't know anything about the reduced sized version, but I used one of the 102' variety for MANY years on a city lot as my only way of getting on 8 megs down to the bottom of 80M. It was hung near 50' at the center and just above fence height on the ends inverted vee style, so the angle exceeded 90 degrees, I am sure. I used it on MARS too on a wide range of frequencies. Is it as good as my full sized 80M dipole at 60' since I have more real estate, probably not, but sure better than trying to tune a coax fed 40M dipole anywhere other than 40M. I never needed to talk to anyone with the G5RV that I couldn't. In other words, if I could hear them, I could work them.

Also, I feed my 80M wire with 300 ohm line from the Wireman (actually his Coaxman component here in Oklahoma) and find it varies less in bad weather like rain, snow, etc. It also seems less susceptable to nearby objects interferring. Just my opinion though, other love their 450 ohm stuff too. I think height and proximity to the transmitter are a problem for a lot of the folks using rigs nowadays. I think the original poster here said 17' was the maximum he could get the center up. That makes it hard to get away from surrounding objects as you mentioned earlier.
As always, YMMV.

The biggest issue with a G5RV antenna is its inability to give good, low SWR on all bands... I **think** it's 17 that won't load correctly, a tuner is mandatory..I don't rightly remember, so don't want to have anyone chisel that in stone. I tried a G5RV at my house and couldn't get it to work across the street, so took it down and put up a coax fed Windom...works beautifully, and on all bands..6 to 160..highest SWR is 1.8 on 40. All other bands it is below 1.4...Even 60 meters is 1.3.3.

The old rule, "Whatever works, is good!"

My initial experience with a 102 foot long G5RV using a Drake MN-4 low power tuner didn't work very well. There wasn't an arcing, the tuner simply didn't work as well with the G5RV. However, when I switched to a Drake MN-2000 tuner the G5RV worked great.

As for WARC bands, I only used the G5RV and MN-2000 on 30 and 17 meters.

I won't comment on any other make and model tuner since I have no experience using any tuner except the Drake MN-4 and MN-2000.

I will not say you will have the same results as I did, it all depends the amount of space you have, how you erect the antenna, etc. I can only say what my experience has been, nothing more.

Have fun.

I have a small garden and use an inverted l with a remote autotuner that has been 'learnt' on all bands used. Of course I tune the rig into a dummy load first then switch to the antenna, flick the send key on and off and bingo. This has got me from the east of the Uk to japan, south Africa, the states and many other places with 59 reports.

Craig,

I have not seen any replies to your question. The 30 series hybird range has an issue with strong signals and the noise blanker, eg: If you have the noise blanker turned all the way clockwise you may have some distortion on received signals, try backing off NB and see how you go, should removed the distortion. As for to schottky or not, personal decision, but if it's not broken why risk the possibility of lifting a track or possibly introducing another problem.

Subject: [TS-520_820_530_830] Schottky or not to Schottky?

Okay, I'm confused.

My TS-830S -- when compared with my super clean sounding TS-530S -- exhibits a slight amount of receiver distortion on strong signals. The 830's frequency response is also not quite as open and transparent as the 530's, though the 830's noise floor sounds lower. Both radios' audio outputs are connected to my SP-230, so speaker response is identical.

Would swapping the 830's 1N60 diodes with Schottky diodes make a positive difference? I have read scores of forum queries on this topic and the answers appear to be almost equally divided between "Wow! What a difference!" and "Don't bother. If it ain't broke...."

I can certainly live with the 830's received audio and am reluctant to mess with any more fragile circuit board traces if the results will be negligible. However, if I can make my 830 sound as smooth and bright as my 530, I'd take the chance.

So, what's your experience, please?

Thanks (again) and 73,

Craig

HI group.

I am working on a 530s. I will be changing the band change coupler. It will need an alienment also, but finding the right tool to do it with has been a challenge. Anybody have source to share? i saw a kit on Amazon, but you cant really see what kind of tips you are getting. The 530s has very small rectangle type tuning slugs.

Also the noise blanker isnt working..any thoughts on that?

thanks

G'day,

Please leave your name and callsign at the end of your message, makes it easier to address you and your specific radio problem. Ken, K3EAA has a great alignment tools and Barb (XYL) is real quick in getting orders out! You can also make your own tools from large knitting needles that can be filed down to your requirement. Be careful when attempting to adjust the slugs as they tend to stick after many years not being move. The preferred method I use is to get a clean solder iron and gently heat the slug and then turn to prevent it re-sealing. There are other methods from using different solvents\lubricants.

As for your noise blank, first try cleaning the switch with a squirt of De-oxit, action the button a number of times then give a good blast of can air, same with the front panel NB adjustment pot. Report back on your findings in case we need to go further.

The 530's noise blanker, unlike Digital Signal Processing, will only respond to ignition noise and the like.

You say the noise blanker isn't working. How do you know for sure it's not working? Have you tested it on pulse type noise such as a hair dryer? If not then try that.

The noise blanker in the hybrids will not eliminate all types of noise. The noise blanker is designed to eliminate arcing or pulse type noise only such as engine ignition noise (spark plugs) or power line arcing. Try the hair dryer test, turn the hair dryer ON and if it produces noise in the hybrid turn the noise blanker switch ON and the noise should be significantly reduced if not eliminated. If that happens then the noise blanker is working.

I forgot the mentioned an additional comment about the noise blanker.

First, I do not have a KW hybrid, sold my TS-520SE many years ago and sold my TS-820 a couple of years ago, but I do have a Heathkit SB-303 solid state ham band receiver that I installed a KW TS-520 Noise Blanker board in. That NB board in my SB-303 receiver is the exact same NB board in the KW TS-520/520S/520SE.

What you will find when the noise blanker is working to eliminate arcing/pulse type noise, the receive signal may appear to be slightly distorted in the speaker. I find this to be more evident on CW rather then sideband signals. I have, however, noticed on sideband if a strong distant station operating 5Khz or so away from my operating frequency, with the NB turned ON with pulse type noise present, the distant receive signal may appear as "splatter". What you are hearing, in most cases, is not "Splatter" at all.

The NB operates on pulse type noise and when pulse type noise is present in the receive signal (the receive signal path goes through the NB whether the NB is turned ON or not), the NB switching circuit switches the signal path OFF and ON very rapidly. The "instant" (a few milliseconds) the noise is detected by the NB, a very small amount of noise will accompany the signal and be heard as distortion in the speaker. This is normal for most all pulse type NBs. The 520 NB in my SB-303 (same NB board in your 520) as well as the NB in my Drake R4B and R4C receives exhibit the same very slight distortion heard in the speaker when pulse noise is present and the NB is turned ON.

If the NB is turned ON but there is no pulse type noise present then you will not hear any difference in the signal nor will you hear any distortion because the NB acts ONLY when pulse noise is present so the signal path remains switched ON by the NB switching circuit.

I was looking for miss titled adds on craigslist for Kenwood gear, and I was able to score a MC-50 with a TS-120S for $175. It has been up for two weeks. I love finding little nuggets like this. I tried it with my old TS-520S last night and received great audio reports.

The TS-120S is alright. It might need an alignment as the sensitivity seemed not to be consistent across the band. I noticed the static as I tuned across the band went up and down in a sinusoidal fashion. The static just seemed like local power line hash we get when there is fog or moist onshore flow. However, band conditions were really weird and noisy last night. Is there an alignment issue that can cause something like this? It is not the best receiver so far, but it is a real talker. I worked Pat, I5ZSS as my first contact on the radio from six land on 40m last night. I was thinking about using it as my field day rig, but I might just flip it and use the money to get an IC-730 for FD.

We have heard a lot about G5RV antennas lately. I can claim over 45
years experience with them fortunately.
There is one BIG problem though, Hasn't anyone in the US or Canada ever
heard of a Z match coupler?
Look it up, if you are curious. That is what I have used for very many
years, both the 2 coil and single coil versions.
My G5RV is fed with ~450 Ohm home made ladder line. I Have had little
success with the old 300 Ohm ribbon
and the original idea of putting a 75 Ohm coax on the end always worried me.
Mine gives virtually unity SWR on all bands except 30 Metres. But even
there there is a cure, just make a heavy wire
self supporting coil of about 1.3 uH and put it in series with one
feeder. With that 10.1 Mhz is flat too.
IMO too many Hams are too fond of coax, it is fine in the shack and for
vertical and UHF/VHF antennas, but when trying to match a wire
antenna over the whole HF range it is more a hinderance than a help and
a big source of mismatch and losses.
My 2 Cents worth from over 50 years on the air.
Zl1BDA.

Did you use the calibrator as a signal source then connect the 120 to a 50 ohm dummy load, first before you considered the 120 receiver may need an alignment? The calibrator signal should be fairly constant, S meter indication, across the band selected. The calibrator signal strength, as shown on the S meter, may be 10 to 20 over 9 on 80 meters, S10 on 40 and S9 on 20, but drop to S7 or less on 15 and 10 meters. If this is how the receiver reacts to the calibrator signal then I would say the receiver alignment is fine. Having said that, the real test is to check the receiver alignment using the 120's service manual receiver alignment steps.

External power line arcing and/or atmospheric "static" noise and band conditions have nothing to do with receiver alignment.

I have noticed that this same insulator arcing is VERY broad banded on my other receivers. However, I concur basing the receiver alignment on this is not very scientific. The problem wasn't very noticeable when I tried it really quickly this morning. The band was VERY noisy last night too. It was an S7 on my 520 sugar before I swapped in the 120 sugar.

What do you think about the possibility of using this rig for field day? I was holding out for an IC-730, but the price was a steal ESPECIALLY with a working MC-50.

Hi Dave,

The noise blanker's not the problem (though I did find it on and cranked up all the way when I first got the radio and discovered what THAT did to the audio). Nevertheless, the problem is so minor that I've decided to leave well enough alone.

As I may have mentioned, if I didn't have the super clean TS-530S audio to compare it with, I doubt that I'd even notice it. Balancing the 830's slight distortion on strong signal peaks is it full, rich frequency response otherwise --much more so that the 530.

Many thanks and 73,

Craig

The true Harvey Wells Z-Match is very hard to find here. I owned one years ago along with Johnson Matchbox and several homebrew balanced transmatches. Can copy the Z-match circuit, but parts hard to find and come at a premium.

Problem today is vast majority of newer hams are buying low cost T-match tuners like the MFJ some of which have a more or less adequate toroid transformer for balanced feeders. Cheaper to buy one of these off eBay than to build a balanced tuner.

These new T-match tuners promote or facilitate the use of coax to feed antennas either multiband or resonant dipoles. I think it is part of reason you see them used frequently to load a commercial triband yagi beam instead of just living with the SWR curves if fed directly by the coax. Very silly. Part of the "1:1-itis" that pervades the ranks.

Also, very few new or old hams are homebrewing tuners. Most do not understand what additional losses the coax presents in presence of the high SWR that multiband antennas exhibit. Also I think they favor coax for ease of entry and routing to the shack.

Not easy to home brew a balanced tuner today as air variables, roller inductors, bandswitches, Air dux coil stock etc are hard to find. Hamfest are not what they use to be. More of social events today.

I always used thermocouple RF amp meters in each leg of my feeders and tuned for maximum. Very easy way to adjust the tuner. Never had an SWR bridge for adjusting balanced tuners feeding multiband antennas back in early days. How often do you see an RF amp meter today?

Very different world today. Almost anything will work to some degree. Definition of work is different to different folks and if the Op is making contacts and is happy then I guess that is all that matters.

Perhaps with time some folks might progress to experimenting with multiband antennas fed with balanced feeders? Just about nothing more fun that experimenting with wire antennas especially if you have the room or trying to be innovative and maximize efficiency using the space limitations that you have.

A few years ago it was all the rage to replace the 1N34 or 1N60 germanium signal diodes in the balanced modulator and the product detectors that were in ring diode configuration with Schottky or hot carrier diodes. It was topic here, Heathkit forums, QRZ, Eham and others. Common diodes included 1N5711, 1N4454, 1N6263 and others.

Many if not most of the reports were anecdotal or feel good engineering and not based on before and after measurements. There are back issues of QST that address this topic.

Have to be careful when you research this as some folks confuse and mix this diode change out with PIN diodes and two very different animals and subjects. Tom W8JI tried to discuss this and he was talking about PIN diodes and not Schottky.

I tried 1N5711s in couple of Hybrids. I dont have necessary test gear for measurements and perhaps I have a less than a discriminating ear. I did not see/hear dramatic improvements.

However, I am in favor of using matched sets of what ever ring diodes you use. Helps with carrier suppression. BFO or CIO leakage back to the IF stages can be a problem as the AGC detector diodes treat that leakage same as they would off air signal.

I think today if you bought a new receiver that uses ring diode product detector (not likely but lets just say if it did) it would be safe to say that it would have hot carrier diodes and not germanium signal diodes. The design engineers have to be specing these for a reason.

So given that it is relatively easy to pull the IF board then go ahead and install matched set of hot carrier diodes in your product detector (you can buy bulk match them and if need help I can give a method). This assumes you have the tools to safely unsolder the old and resolder the new. Not worth lifting a foil or pad.

At same time use this opportunity to carefully inspect all the Molex connector pins to ensure no bad solder connections. Need magnifier and good lite.

If you do try them I would be interested in your report (subjective or otherwise) on what improvement you notice.

Craig,

I have not seen any replies to your question. The 30 series hybird range has an issue with strong signals and the noise blanker, eg: If you have the noise blanker turned all the way clockwise you may have some distortion on received signals, try backing off NB and see how you go, should removed the distortion. As for to schottky or not, personal decision, but if it's not broken why risk the possibility of lifting a track or possibly introducing another problem.

Subject: [TS-520_820_530_830] Schottky or not to Schottky?

Okay, I'm confused.

My TS-830S -- when compared with my super clean sounding TS-530S -- exhibits a slight amount of receiver distortion on strong signals. The 830's frequency response is also not quite as open and transparent as the 530's, though the 830's noise floor sounds lower. Both radios' audio outputs are connected to my SP-230, so speaker response is identical.

Would swapping the 830's 1N60 diodes with Schottky diodes make a positive difference? I have read scores of forum queries on this topic and the answers appear to be almost equally divided between "Wow! What a difference!" and "Don't bother. If it ain't broke...."

I can certainly live with the 830's received audio and am reluctant to mess with any more fragile circuit board traces if the results will be negligible. However, if I can make my 830 sound as smooth and bright as my 530, I'd take the chance.

So, what's your experience, please?

Thanks (again) and 73,

Craig

If it is something you can link to or copy/paste into an email, I would be interested in your method for matching diodes. I'm not wishing to put you to a lot of typing, though, so don't go out of your way for this.

At the moment it's idle curiosity, too much else to do. Although the sheer amount of noise on the receiver of my 520SE (with a dummy-load for an "antenna") was a bit off-putting to me, and lower the noise figures would be a good thing.

I'm going to be using the antenna analyzer as a DSP (it has the daughter board for it) when it is all finished, but if there is a way to give the DSP less noise to work out to begin with, that would be a boon.

(Also I'm curious what sort of circuit you're going to use. I -know- you are not talking about just using an ohmmeter to check the junction voltage drop.)

No I dont use ohm meter or diode test function on the DMM. Diode test function may not have sufficient current flow.

I build a simple series circuit and use a regulated DC supply to feed it and measure the voltage drop across the diode to 3 places with a DMM. Go thru the batch and select 4 that have very close to same voltage drop. Regulated supply is a must.

If you do not have a regulated low voltage DC supply then buy couple of fresh 6 volt lantern batteries.

Place approx 4.7k ohm resistor in series with your diode under test and connect the regulated DC supply across both. I use 12 vdc. Place your DMM on low dc voltage range and measure the voltage across the diode to 3 decimal places. The 4.7k resistor limits the current. 12/4700 = 2.5ma. You want some current flow to allow diode to temperature stabilize.

Wait about 10 seconds before recording the voltage drop so diode will temperature stabilize. You can connect meter right away or after warm up time. Connect your DMM across the diode and measure the voltage to 3 decimal points. Log this value for this diode.

Select the next diode and place in circuit and again wait a few seconds to allow diode to stabilize and measure the voltage drop across it to 3 places. Log this value.

Go thru your bulk batch of diodes and just select 4 diodes that have very close to the same voltage drop.

I generally would not use much more than 5 to 10 ma of current.

Perhaps other members have a better method?

45045. TS520 Calibration and tuning strangeness

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-04 21:09:16 UTC
From: Gordon JC Pearce
Topic: 45045 Message: 45045

Hi folks,
I finally decided to take a look at how well tuned the calibrator is on my TS520, and correct the sub dial being about half a notch off when set to zero.

What I'm puzzled by is this - the manual suggests that on CW the RX offset should be about 700Hz to give a nice CW tone, and on TUN there should be no offset so the radio will transmit at the same frequency it receives - so when I zero-beat to a known 7.000MHz oscillator I am transmitting on 7.000MHz with the offset only coming in when I switch to CW.

So, this sounds like I should hear a shift of around 700Hz if I switch between CW and TUN, but I don't.

Looking at the voltages on the select pins on the carrier board, in both CW and TUN the CWR pin is at 9V and the CWT pin is at around -1.8V. These swap over when I switch to transmit. The position of the CAL switch makes no difference.

Looking at the circuit diagram I have (from KG6HAF's site) it looks like CWT should be fed off the regulated +9V rail in tune, no matter what. CWR looks like it might be fed from the RL1/4 contact, but I can't see what would cause it to turn off for tuning. It may be that the diagram isn't accurate.

Anyway, thoughts?

Shucks. I thought maybe you had some sort of bridge in mind.

I have been matching diodes using voltage drop measurement since high school. (Of course, some of them were TUBE diodes back then, and the circuits were a bit messier, the drops were quite a bit more than .7V, but it's still mostly the same, no?)

I should have mentioned if the CW filter is installed, the TS-120 becomes a very simple and nice CW, as well as a sideband, transceiver. I spend most of my time on CW but ever once and awhile I do get on sideband. The only experience I have with a TS-120 is when I repaired one for an old ham friend of mine who is now a SK. I did enjoy how simple it is to use.

I do not have any experience operating an Icom 730 so I won't comment on that radio.

I will say I don't care for radios that have a lot of buttons that control features I most likely will never use. The same goes for radios that have all those menus that control features I also will not likely use. So, whether you select a TS-120 or the IC-730, is entirely up to you.

Most of my radios are vintage, Drake B and C Line, Heathkit SB-100/HW-101, DX-40 with HG-10B VFO and a Heathkit SB-303 solid state ham band only receiver. I really enjoy operating the DX-40 and HG-10B VFO combination, 45 watts output on CW and AM, is a challenge and a lot of fun. I've been told, "you can connect the DX-40 to your AL-811 and you will have a very nice CW and AM signal". Well that may be true but using the amplifier with the DX-40 defeats the purpose of operating low power now doesn't it?

Small knobs, a lot of menus, LED screens, and lots of buttons are what I don't like about modern day radios. Besides the high prices, the small knobs, lots of menus that control features I will never use, and all those buttons on the front panel is why I haven't and probably will not purchase a modern radio. I also will not pay more for a radio than what my monthly mortgage payment is (PITI). But, that's me.

I tested it with the CAL. All seems fine. S-9 +5 on all bands accept 10m.
That was S-7. The RIT switch is a little squirrely, but nothing a shot of
Deoxit can't fix. I also have a DX-40 that I got for free at a ham meeting
a while back. I haven't messed with it much. You inspired me to stick it
on the bench, and give 'er a go.

DX-40 running full power out without a key (40W). Something is a miss :D
It came with three x-tals. Now I am dying to get this old gal running.
It has a nice T/R relay in the back too. I am ready to rock. I just need
to trouble shoot why it is going full output without a key.

Regards,
Chris Maness KQ6UP

There is a shorting contact in the key jack the completes the circuit when the key is removed.

There is nothing wrong with it. Just insert an unwired 1/4" phone plug.

DX-40 running full power out without a key (40W). Something is a miss :D It came with three x-tals. Now I am dying to get this old gal running. It has a nice T/R relay in the back too. I am ready to rock. I just need to trouble shoot why it is going full output without a key.

I should have mentioned if the CW filter is installed, the TS-120 becomes a very simple and nice CW, as well as a sideband, transceiver. I spend most of my time on CW but ever once and awhile I do get on sideband. The only experience I have with a TS-120 is when I repaired one for an old ham friend of mine who is now a SK. I did enjoy how simple it is to use.

I do not have any experience operating an Icom 730 so I won't comment on that radio.

I will say I don't care for radios that have a lot of buttons that control features I most likely will never use. The same goes for radios that have all those menus that control features I also will not likely use. So, whether you select a TS-120 or the IC-730, is entirely up to you.

Most of my radios are vintage, Drake B and C Line, Heathkit SB-100/HW-101, DX-40 with HG-10B VFO and a Heathkit SB-303 solid state ham band only receiver. I really enjoy operating the DX-40 and HG-10B VFO combination, 45 watts output on CW and AM, is a challenge and a lot of fun. I've been told, "you can connect the DX-40 to your AL-811 and you will have a very nice CW and AM signal". Well that may be true but using the amplifier with the DX-40 defeats the purpose of operating low power now doesn't it?

Small knobs, a lot of menus, LED screens, and lots of buttons are what I don't like about modern day radios. Besides the high prices, the small knobs, lots of menus that control features I will never use, and all those buttons on the front panel is why I haven't and probably will not purchase a modern radio. I also will not pay more for a radio than what my monthly mortgage payment is (PITI). But, that's me.

Did you use the calibrator as a signal source then connect the 120 to a 50 ohm dummy load, first before you considered the 120 receiver may need an alignment? The calibrator signal should be fairly constant, S meter indication, across the band selected. The calibrator signal strength, as shown on the S meter, may be 10 to 20 over 9 on 80 meters, S10 on 40 and S9 on 20, but drop to S7 or less on 15 and 10 meters. If this is how the receiver reacts to the calibrator signal then I would say the receiver alignment is fine. Having said that, the real test is to check the receiver alignment using the 120's service manual receiver alignment steps.

I will give this a shot.

External power line arcing and/or atmospheric "static" noise and band conditions have nothing to do with receiver alignment.

I have noticed that this same insulator arcing is VERY broad banded on my other receivers. However, I concur basing the receiver alignment on this is not very scientific. The problem wasn't very noticeable when I tried it really quickly this morning. The band was VERY noisy last night too. It was an S7 on my 520 sugar before I swapped in the 120 sugar.

What do you think about the possibility of using this rig for field day? I was holding out for an IC-730, but the price was a steal ESPECIALLY with a working MC-50.

I was looking for miss titled adds on craigslist for Kenwood gear, and I was able to score a MC-50 with a TS-120S for $175. It has been up for two weeks. I love finding little nuggets like this. I tried it with my old TS-520S last night and received great audio reports.

The TS-120S is alright. It might need an alignment as the sensitivity seemed not to be consistent across the band. I noticed the static as I tuned across the band went up and down in a sinusoidal fashion. The static just seemed like local power line hash we get when there is fog or moist onshore flow. However, band conditions were really weird and noisy last night. Is there an alignment issue that can cause something like this? It is not the best receiver so far, but it is a real talker. I worked Pat, I5ZSS as my first contact on the radio from six land on 40m last night. I was thinking about using it as my field day rig, but I might just flip it and use the money to get an IC-730 for FD.

Topic: 44440 Message: 45052

It is advantageous to test match diodes at more than one current level. For example, a batch should be measured at, say, 3 levels, <0.5 ma, ~2ma and ~5ma. Or, maybe 0.3ma, 1.5ma, and 7.5ma. Then choose the 4 that are closest to matching Vf at all 3 currents. A curve tracer would be best, but not many of them around anymore. A stable high voltage supply and a suitable series R will put you in the ball park on these current levels, just use a really good DVM to test forward voltage. The reason for 3 different test levels is to match the curve of the diode rather than a spot current. This will improve distortion.

Schottky diodes are used for lower noise and higher dynamic range in diode mixers. Germanium has some nice detector characteristics for low barrier voltage without much forward current, but they are not the best for mixer applications.

FWIW, Schottkys can be purchased in sets of 4 matched parts in a single package. HP, now Avago, sells these as part number HSMS-2829 for a crossover ring configuration or as HSMS-2827 for a classic ring. They are available in 4 lead SOT23 packages which, though small, are pretty manageable to handle and wire into circuit. Their data sheet says:

“These Schottky diodes are specifically designed for both analog and digital applications. This series offers a wide range of specifications and package configurations to give the designer wide flexibility. Typical applications of these Schottky diodes are mixing, detecting, switching, sampling, clamping, and wave shaping. The HSMS-282x series of diodes is the best all-around choice for most applications, featuring low series resistance, low forward voltage at all current levels and good RF characteristics.”

Digikey lists them but with 0 available. Prices are < $2.00 in low qty. Mouser has a few of the quad ring available and quite a few of another quad ring style package, the HSMS-282R, which will work as well, just a different small package. For the effort to match these and the cost of buying a reasonable quantity to test for match, these quad and crossover matched diodes are a bargain. They are specifically made for these applications and they are not expensive. You can’t match them for what these cost, but you will need a magnifier and a steady hand to wire them in—not that difficult.

this posting system is a bit confusing But...glad to see I got some replies. The blanking out is not longer a problem. i took the CB mod out which was two wires on the board above the VFO that were cut and switched it and out or tied to together. i just cut out the switch and resoldered the wires back together...matching colors.
In the process, i also figured out the the WARC band have never been activated. I found the blue wire and snipped it...and now i have warc bands. The 30 meter band is very low. i think maybe an alinement is in order, but i need to find the right tool. Ken, K4EAA says he uses Popsicle sticks sometimes

Subject: Re: [TS-520_820_530_830] RE: 520s send/rec switch not working

Steve,

Welcome to the phrase "CB HACK" or "FREE BANDING." Without going into detail..the "mod" allows the rig to receive and transmit
in the CB and other non-ham band areas Generally, from about the low 26Mhz area and up above 29Mhz. This mod is usually easy to remove, unless the
hacker has cut some diodes on the "digital readout" board...then it could become a problem re-doing the diode(s) leads. I have also seen
the PLL board hack...but I have not seen it as much as the above mentioned. Also, the famous "QRO" mode could have been done to get
every last milliwatt of power out of the finals...this is stupid and causes damage to numerous components. The most common QRO mod is moving
1 wire from the "210" post to the "300" post on the rectifier board. This raises the voltage to the final tubes screens...thus "more power." Also, changing
the value of the 470 ohm resistor..which I think is R-11 on the rectifier board. Compare the wires you SEE to the wiring schematic.

As far as the band "blanking out"...could be a couple of problems...MOST common is the "wiper" inside the VFO unit has gotten some gunk/corrosion
on it. The VFO is easy to remove..using the 4 screws on the front. Pull out slowly..as there are wires connected to it for the voltage/signals and for the

lights. I usually do this with the rigs top and bottom covers removed....rig UNPLUGGED from the power(my standard disclaimer). Remove the dial lamps and,
the connector on the rear of the VFO...it just un-plugs. Remove the screws holding the cover in place...the wiper is at the rear..use some contact cleaner...operate
the VFO through its travel several times...blow off with "canned air" and repeat once...you can reconnect the connector on the rear...turn rig back on and check for
proper operation before fully reinstalling it. Try this first and let us know

Subject: [TS-520_820_530_830] RE: 520s send/rec switch not working

I hate to add to my last topic with a different topic. But I am having problems finding the post button. Is it me or is this new format a problem for everybody.

I just came into a 530s. there is a 28MHZ mod that i would like to rid myself of. looks obvious on the surface. a 2 position switch and 4 wires making and breaking some wires going to the VFO board. Anybody know if there are more mods to be on the look out for, maybe some that are not as obvious as a switch and bell wire being strung here and there. The digital display will also blank out from time to time, either when band switching or just tuning across the dial on some bands.

I am looking for info on the 530s including how to do an alignment, etc..the basic stuff. but like I said before I am having problems navigating this forum now.
So far it seems to tune up on 20m but not so much on 40m. made some contacts, VFO seems to be on target, audio is good. Anything to look for that 530s are known for? My Other rig is the 520s

again thanks for the input guys

steve

Subject: RE: Re: [TS-520_820_530_830] 520s send/rec switch not working

Thanks Joe..and the rest of the thread.

Tonight the switched worked. overtime and on 80 meters as well as 20 meters. Either I have an intermindant or perhaps i didnt give the heater enough time to warm up. But now that its working, its hard to trouble shoot. If i have to go in for another reason, I'll check the relay and get it cleaned up..or replaced. The good news is I went and got some more canned air for the occasion and it was on sale for 10 bucks for 3 cans. so now i am well stocked.

Thanks everybody.

steve

Steve,

I would suspect RL-2 first, it's under the metal shield by the final amp board. UNPLUG RIG!, let it sit, then check
to see if there's anymore high voltage lurking around. Remove shield...remove relay (it pulls out), you will need a fine
screwdriver or similar tool to remove the plastic cover from the relay. Use some card stock wetted with contact cleaner
and clean all the contacts...some canned air comes in handy here. Re-install relay and check for operation.
There's kinda of a clue here too: 80 meters has not been used in "a long time." The bandswitch wafer contacts
may have gotten some corrosion on them from no use, but worked correctly on 20 meters. Clean all the bandswitch wafer
contacts with contact cleaner/lube and blow off with canned air. I'll wager that all should be fine now

Subject: [TS-520_820_530_830] 520s send/rec switch not working

Hi Group, sorry if this has been posted already, but i am having problems find things here with the new group look.

After many, many years my send/rec switch stopped operating.(TS-520S) It fires the relay occasionally. It started when i tried to tune on 80 meters for the first time in a long time. Click, and nothing. Switched back down to 20 and it worked intermediately. So from past experience, would this be the switch, the relay, or power to the relay? .....Possibly

the band switch??

I havent begun to even look at it yet tonight..too late to start. I will try keying the relay via the mic tomorrow, and a few other things. I wanted to get a post going so i'll have some input to think on while I look at the schematics.

Thanks

Steve

Hi guys,,,I dont know where my post went, maybe into the land of rare DX . Strange thing is I saw a reply last night, where someone suggested K4EAAs site..oh well....but I was wondering if anybody has seen where to get alignment tools for the 530s. Ken sells them for the 520, but not the 530.
Also the noise blanker isnt working. Any ideas.

Also 30 meters is very low on recieve, all other bands okay. anything there besides an alignment?

steve

Larry:

Thanks for sharing.

I thought about mentioning the Octopus Curve Tracer adapter that can be used with O-scope XY, but have no experience with it and suspect it would not be adequate.

At one time I looked for Tektronix 576 units and find them, but not usually less than $1000.00.

W2AEW has a video on You Tube that demonstrates the Octopus adapter.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

It is advantageous to test match diodes at more than one current level. For example, a batch should be measured at, say, 3 levels, <0.5 ma, ~2ma and ~5ma. Or, maybe 0.3ma, 1.5ma, and 7.5ma. Then choose the 4 that are closest to matching Vf at all 3 currents. A curve tracer would be best, but not many of them around anymore. A stable high voltage supply and a suitable series R will put you in the ball park on these current levels, just use a really good DVM to test forward voltage. The reason for 3 different test levels is to match the curve of the diode rather than a spot current. This will improve distortion.

Schottky diodes are used for lower noise and higher dynamic range in diode mixers. Germanium has some nice detector characteristics for low barrier voltage without much forward current, but they are not the best for mixer applications.
FWIW, Schottkys can be purchased in sets of 4 matched parts in a single package. HP, now Avago, sells these as part number HSMS-2829 for a crossover ring configuration or as HSMS-2827 for a classic ring. They are available in 4 lead SOT23 packages which, though small, are pretty manageable to handle and wire into circuit. Their data sheet says: “These Schottky diodes are specifically designed for both analog and digital applications. This series offers a wide range of specifications and package configurations to give the designer wide flexibility. Typical applications of these Schottky diodes are mixing, detecting, switching, sampling, clamping, and wave shaping. The HSMS-282x series of diodes is the best all-around choice for most applications, featuring low series resistance, low forward voltage at all current levels and good RF characteristics.”
Digikey lists them but with 0 available. Prices are < $2.00 in low qty. Mouser has a few of the quad ring available and quite a few of another quad ring style package, the HSMS-282R, which will work as well, just a different small package. For the effort to match these and the cost of buying a reasonable quantity to test for match, these quad and crossover matched diodes are a bargain. They are specifically made for these applications and they are not expensive. You can’t match them for what these cost, but you will need a magnifier and a steady hand to wire them in—not that difficult.

Topic: 45036 Message: 45057

The CW key socket in the DX-40 is a "N.C." socket. This means if a 1/4" mono plug is not inserted in the CW key socket the transmitter will be keyed IF the Function switch is placed in "PHONE" or "CW". Do not key the DX-40 without a crystal or a proper VFO signal applied. There isn't any protective bias or Clamp tube circuit in the final amplifier that cuts the final tube OFF when loss of RF drive to the final tube occurs and the CW keying circuit is shorted to ground. Loss of RF drive will result in full scale, well over 150ma, plate current to flow in the final tube if you key the DX-40 without a crystal or a proper VFO signal applied to the rear VFO socket. The DX-40 uses "Cathode keying", a DC voltage of approximately 130VDC is present on the CW key socket and CW key terminals regardless of PHONE or CW modes. Also, do not key any VFO that's providing a signal to the DX-40. The chances of chirp are rather high. I do not key the HG-10B VFO I use with the DX-40 which results in no chirp in my transmit signal. I control the VFO "Key" socket through a relay terminal. Let me know off group if you would like to see how I do this, it's real simple. I have a few more things I did to my DX-40 so if you want to discuss this further, let me know off group through private email.

I apologize to the group for taking up time on the group with non-Kenwood discussion(s).

Oh dear! Please don't depress me more than I am already!
Do you mean to say that the average Ham these days can't even build themselves a simple transmatch.
The Z match needs 1 coil (with a couple of taps) 1 link coil and 2 tuning capacitors.
Over the years I have been VERY unimpressed with the commercial Transmatches that I have come across
they tend to use highly stressed components and have a lot of hot toroids in some also.
Unless you are using over 200 watts or so even the larger air spaced tuning caps from valve radios will do.
BTW there are dozens of designs, with pictures on line also, for all power levels.

Of course I have been doing electronics for well over 60 years. But even at 9 years old I was able to build and
adjust a Crystal set and by the time I got my licence in 1958 I was using a mixture of war surplus and home brew
gear.
In other words, it really isn't that hard to get a basic technical knowledge of electronics if a 9 or 10 year old can
do it.
So what is the point of becoming a Ham these days if you aren't interested in the subject?
After all we didn't have the Internet so pure communication was a big thrill back then.
As usual I must really be getting old!!!
Zl1BDA.

Steve,

  I have used the "alignment tool set" from "Amazon" that your were talking about in your original post. The thing that you
will have to do is take a very sharp knife...say an exacto...and trim back some of the plastic as the end is at times too short
to get to the slug, as the shoulder of the tool can hit on the top of the "can." Or, go to a hobby or craft store and look for a piece
of plastic rod that you can "custom" make your own...or a nice piece of dowel stock.

 I do not know enough about the noise blanker circuit to offer a logical/correct answer. I think that Terry-k9tw, just answered
something about a noise blanker a few posts ago.

As far as 30m goes...check for proper adjustment of the associated coils first. Can you get a good "cal signal?"

Joe,
On some of the slugs, it is hard to get a tool that actually fits
correctly.
I have learned if I heat the end of an old tool with my hot *air
*soldering iron until it is soft,
then push it down against the slug and let it cool in that position,
After it fully cools, I now have a tool that now fits the slot perfectly!!
I do this with old tools that the end has worn down on so It makes them
useable for something without throwing them away.

No Joe, I dont get a good cal sig on 30. most other bands are close to or at S9, Thats what makes me wonder if its not "something else"

There are two tool sets on amazon..one have 5 pc the other 12 (I think) which one did you get?

thanks

I do not know enough about the noise blanker circuit to offer a logical/correct answer. I think that Terry-k9tw, just answered
something about a noise blanker a few posts ago.

As far as 30m goes...check for proper adjustment of the associated coils first. Can you get a good "cal signal?"

Hi guys,,,I dont know where my post went, maybe into the land of rare DX . Strange thing is I saw a reply last night, where someone suggested K4EAAs site..oh well....but I was wondering if anybody has seen where to get alignment tools for the 530s. Ken sells them for the 520, but not the 530.

Also the noise blanker isnt working. Any ideas.

Also 30 meters is very low on recieve, all other bands okay. anything there besides an alignment?

I have new cathode, screen resistors coming from Ken. What should I be measuring across the resistors in circuit? 10 ohms on the cathods? I measure 8 ohms

Joe,
On some of the slugs, it is hard to get a tool that actually fits correctly.
I have learned if I heat the end of an old tool with my hot air soldering iron until it is soft,
then push it down against the slug and let it cool in that position, After it fully cools, I now have a tool that now fits the slot perfectly!!
I do this with old tools that the end has worn down on so It makes them useable for something without throwing them away.

45068. Ladder line vs, coax. Scarcity perhaps?

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-05 07:09:34 UTC
From: Wes Will
Topic: 45059 Message: 45068

New subject, same topic. Z-matches, lack of electronic gadgeteering on the part of the new meat, and co-axial abundance.

One of the reasons coax is so prevalent is that it is easy and fairly cheaply come by. Ladder line you never see any more, but I can get miles of coax at the local radio hack store. (Another lament there, the downfall of R.S. and I really miss the Lafayette store...)

Anyone got a good source for 450 ohm ladder line? Cheap? Or a better tip than anything I know for sourcing or making a few hundred insulator spacers to make my own? I'm not that good at whittling, so that's out. I'd much rather make ladder line, but it has been a long time. Guess it is time to dig out the 1966 ARRL handbook and see if there is any magic to be found inside on this topic.

As for the fresh cheese knowing nothing about electronics, it's probably our generation's fault, or at least we're partly to blame. It's my generation that made everything so small and user-un-friendly on the inside. Not like when I was a kid and could scavenge literal barrels-full of tubes and transformers and such from junked, point-to-point-wired TVs and radios and such.

Now, all the hardware that is available is miniaturized, surface-mounted, and epoxy-potted to keep prying fingers out. It's a bit harder to open up stuff out of curiosity and try to figure out how it works. (And safer, since everything seems to be 5VDC or so, instead of B+ and flyback voltages in the kilovolt or higher range, so there are some gains here. Fewer fried offspring.....)

And Z-matches, yes, they're easy to make, but without that tinkering background as a starting point, quite frankly they're not exactly intuitive when a non-electronic neophyte looks at them or the circuit. -I- get it, -you- get it, but young Joe TechPlus over there, with his solid-state everything hasn't a clue.

Rather than bemoan it, my take is to try and catch 'em as young as possible and give them stuff to take apart and put together again. Even put together broken will help kids get some feel for the insides of gear. AND gives me an opening to show them how to unscrew the inscrutable and make the whatever-it-was work again. When it does, they get a bit of an epiphany a lot of times, and the next step is easier.

It's why I go to my wife's little back-woods-village school***, and do all kinds of "science stuff" with the kids, starting in third grade and going to the high school as often as I can. Everything and anything from cheesy Estes model rockets to raising frog spawn to kitchen chemistry to ham radio and electronics. I try to go at least one or two

times a week, to one or another classroom, since I'm medically retired there's not a lot for me to do except keep the dogs company at home. I try to do something useful, and this is what I've chosen.

And every now and then you see the lights go on in some kid's eyes. Makes it all worth it.

I'm NOT trying to tell anyone what they should be doing. But perhaps if you look around, and if this lack of clued-in-ness in the younger generation really bothers you, maybe you can figure out something similar that makes a difference? Doesn't have to be with kids at a school, doesn't have to be anything at all, if that's what you decide. But I suspect that all of us "Aulde Phartes" can make a difference if we ganged up on the problem. (And frankly, it's a hoot. More fun than watching the dogs sleep, that's for certain.)

(*** "Cobden, Illinois, Home of the Appleknockers" and I kid you not. An "appleknocker" used to be a worker in the orchards with a pole, whose job it was to whack apple trees and peach trees which had too many fruits per branch on them, and remove the excess so the ones that were left could grow properly and mature, rather than just breaking the branch off from being overloaded.)

JSC makes ladder line and you can get it at HRO and other places.

The plastic epoxy encapsulation on semiconductors is not really to keep your prying fingers out but to protect the bond wires (smaller than a human hair in diameter) and to protect the die from contaminants.

Hi Craig,

I managed to buy a 530s and 830s from a SK, had my work cut out on both of them, both had weird faults, hence why I have hands on experience with the PA padder issue. Anyway, I put both of these radios against my originals and they are extremely sensitive, some of the caps on the AF boards have been changed out to tandelums, but saying all this only about 1dB different and the NBs are as different as chalk and cheese.

Subject: Re: [TS-520_820_530_830] Schottky or not to Schottky?

Hi Dave,

The noise blanker's not the problem (though I did find it on and cranked up all the way when I first got the radio and discovered what THAT did to the audio). Nevertheless, the problem is so minor that I've decided to leave well enough alone.

As I may have mentioned, if I didn't have the super clean TS-530S audio to compare it with, I doubt that I'd even notice it. Balancing the 830's slight distortion on strong signal peaks is it full, rich frequency response otherwise --much more so that the 530.

Many thanks and 73,

Craig

Not talking about any single semiconductor. Heck, the glass or metal envelope keeps you from getting to the anode and grid of a tube as well.

I'm talking about potting the whole device. Dog tracking collars, for one, my brother works for one of the manufacturers and they pot it for shock resistance, water resistance, and to keep end-user fingers out. Good idea in the case of the collars, but there are other things, like video game gadgets for instance, which could be fun for someone say, 12 or 13 years old, who got curious and wanted to see what was inside a broken one.

Maybe to scavenge the r.f. modulator section or other parts out of it, or maybe fix it and get some more use from the thing. Open the box and there is a big blob of epoxy. No access whatsoever.

Not wanting to get inside a 555 timer chip. Want to see what the rest of the device the 555 is -part of- does.

Does that get the idea across better?

Hi Ron,

Have you tried grounding pin 2 on the MIC socket to see if the relays energize? Pin 2 on the MIC socket is in parallel with the SEND switch.

The meter switch settings are not enabled in receive. The 820 has to switch to transmit (relay on the RELAY Unit) must energize for the meter switch settings to work.

It appears you may not understand parallel resistor circuits. Therefore,
if I may suggest you take some time and watch my Ohms Law covering
parallel resistor circuit, see the following link:

http://www.n6wk.com/w5rkl/Basic%20Ohms%20Law/

and watch my video on the TS-520 and TS-820 cathode and IP metering circuit

http://www.n6wk.com/w5rkl/TS-520%20and%20TS-820%20series%20Cathode%20and%20IP%20metering%20circuit/

If the total resistance of your final tube cathode reresistors in
parallel is 8 ohms then one or more of the cathode resistors has
increased in value.

If you are measuring the combination of the parallel cathode resistors at 8 ohms instead of 5 ohms, that is not uncommon as the individual resistors do tend to drift high in value with years of service. Pretty common to measure the parallel combination and find 7 ohms to 8 ohms instead of 5 ohms.

You may also be seeing some resistance due to problems with your meter test leads so short them and see what meter reads and then subtract that value from you reading. Meter leads should be very low resistance probably never more than 0.05 ohms. If that is range you find then no need to consider meter leads with any resistance measurements. If using alligator or mini-grabber test leads measure them as they can be bad. Low cost mini-grabbers are notorious for having high resistance connections.

If 8 ohms is accurate it is not any thing that precludes operation of the rig as it places rig in conservative position as it displays plate current (Ip) falsely high. So you are not loading as high as you think you are.

However, I would change them when time permits. Wont hurt to change the 100 ohm grid stoppers and the 470 ohm SG supply series resistor that comes in Kens kit. Typically no need to change resistors that have not changed value beyond tolerance, but these like the cathode resistors have seen a lot of hours. Of course if these show any sign of overheating and discoloration then need to change them.

Terry K9TW.

Guys,
Heard no mention of "Window Line" which is 450 Ohm.
Granted it is not the "Original" ladder-line,
but I have used it to feed my Vertical , and Long-Wire,
pulling the wires directly into the Antenna Tuner as if
they were Coax Feeds.
SWR was adjusted directly on the Antenna this way,
without any interference from the Coax.
SWR was 1.1 : 1 .

MFJ and others have some.

Running my Kenwood, at 3 watts, QRP / CW, on 20M , now.
Good receiver.

Not talking about any single semiconductor. Heck, the glass or metal
envelope keeps you from getting to the anode and grid of a tube as well.

I'm talking about potting the whole device. Dog tracking collars, for
one, my brother works for one of the manufacturers and they pot it for
shock resistance, water resistance, and to keep end-user fingers out.
Good idea in the case of the collars, but there are other things, like
video game gadgets for instance, which could be fun for someone say, 12
or 13 years old, who got curious and wanted to see what was inside a
broken one.

Maybe to scavenge the r.f. modulator section or other parts out of it,
or maybe fix it and get some more use from the thing. Open the box and
there is a big blob of epoxy. No access whatsoever.

Not wanting to get inside a 555 timer chip. Want to see what the rest
of the device the 555 is -part of- does.

Does that get the idea across better?

Hi Ron,

Have you tried grounding pin 2 on the MIC socket to see if the
relays energize? Pin 2 on the MIC socket is in parallel with the
SEND switch.

The meter switch settings are not enabled in receive. The 820 has
to switch to transmit (relay on the RELAY Unit) must energize for
the meter switch settings to work.

to get to the slug, as the shoulder of the tool can hit on the top of the "can." Or, go to a hobby or craft store and look for a piece
of plastic rod that you can "custom" make your own...or a nice piece of dowel stock.

I do not know enough about the noise blanker circuit to offer a logical/correct answer. I think that Terry-k9tw, just answered
something about a noise blanker a few posts ago.

As far as 30m goes...check for proper adjustment of the associated coils first. Can you get a good "cal signal?"

Hi guys,,,I dont know where my post went, maybe into the land of rare DX . Strange thing is I saw a reply last night, where someone suggested K4EAAs site..oh well....but I was wondering if anybody has seen where to get alignment tools for the 530s. Ken sells them for the 520, but not the 530.

Also the noise blanker isnt working. Any ideas.

Also 30 meters is very low on recieve, all other bands okay. anything there besides an alignment?

I am sorry Mike:

TURN THE HEATER SWITCH OFF MAN!

Why would you have the filaments on when troubleshooting a relay keying problem? There is no reason to have the heaters on until a few minutes before ready to load and transmit. Tubes only have so much life and running heaters all the time is not necessary.

If heaters are off then can be no cathode emission and if you lose cut-off or operating bias there will be no Plate current.

Likely you have lost the final tubes. They do not like thermal run away. How did you see the plate glow? Do you have the PA cage cover off? If so why? Have to be very careful with 900vdc present here.

Will let Mike help you trouble shoot this problem as well as the relay keying issues. Not likely related.

Just do not put heaters back on while working on the relay keying problem.

Terry K9TW

Hi Ron,

Have you tried grounding pin 2 on the MIC socket to see if the relays energize? Pin 2 on the MIC socket is in parallel with the SEND switch.

The meter switch settings are not enabled in receive. The 820 has to switch to transmit (relay on the RELAY Unit) must energize for the meter switch settings to work.

Some good points there OM. As it happens I give the occasional science lessons at our local schools
and as an amateur astronomer I take my 8" portable scope around the schools for daytime events like
the recent Transits of Mercury and Venus and a partial eclipse of the Sun. I also do historical reenactment.
I get involved with holiday projects at our local library and even the Kindergarten as well.
BUT you have a very good point about modern "hands off" electronics. I was fortunate in that when I was
about 13 my Uncle gave me a whole lot of 1920's and 30's components (unused) from a local radio shop.
These were the ones with terminals, so I could build up a lot of basic sets like a Meccano (Erector) set.
Perhaps that's where I really got started!
When you get into modern TV etc you realise that there is almost nothing that can be used elsewhere.
In fact the speakers are about IT these days.
Perhaps it is not surprising that I have always been a "young" Ham. Even at 73, many of my fellow ZL's are in their
80's or even like an OT I met the other day who was 96 and still on the air.
Maybe we are getting like those guys who still drive horse drawn carriages as a hobby, though I often wonder what
drastic effect a collapse of our technical base could have as things are now.

But for all that it still seems to me that something as "easy" as a Z match (no more complex than a crystal set)
should not be beyond the skills of someone with a genuine interest in electronics. Don't you have "Junk Sales"
and swap meets any more in North America to find some suitable parts?

I wouldnt concern myself too much about differences in the KW Hybrids unless you are still shopping. Time to do that was prior to shopping and buying.

Assuming you plan to keep and operate this rig you need to gather the documentation for the TS-520 with the Operating Instruction Manual and Service Manual the primary documents that you will need for starters. Start reading and familiarizing yourself with the controls beginning with the setting and operation of the receiver controls.

You will be anxious to try the radio when it arrives. I advise not to be in too big a hurry. Do not turn the Heater switch on. Make sure the Send switch is not flipped to Send. Read section on how to pre-set the controls for receive mode. I would flip the SG switch on rear panel to OFF until ready to think about loading the rig.

Question you should be asking is.....What visual inspections and testing is recommended before plugging in this radio and powering it on? Can I just plug it in and turn it on? There will be varying opinions on this. At minimum I would do a good visual inspection.

Also what auxiliary equipment do I need (dummy load is a must) and what test equipment will I need?

Might help if you have some rig history to provide if you know. Is it a eBay purchase?

What is your back ground and experience level?

These are things that will help people here help you. Lot of TS-520 knowledge and experience here.

Should be a fun experience for you, but can be a frustrating and painful experience.

Good day all!
Stone Me! Whatever happened to "Do it Yourself"?
Buying ladder line!!!!
I have used 2 things as insulators. One is of all things artificial insemination polystyrene tubes
(for cows) which are freely available and very cheap (preferably unused!!!), this cut into about
60 mm lengths can be melted on to the multi strand copper wire used for the feeder with a soldering iron and lasts
for quite a few years. Just stretch the wire for the feeder out in parallel and melt the polystyrene on every 300mm
or so. If you don't live in an agricultural area like me, or want an alternative you can use the plastic slides which support circuit boards in racks. There is a lot of this around from older computer gear and this works just as well. The only thing is to put the slot at the bottom so rain, snow etc doesn't short out the signal.
BTW be careful not to burn yourself, hot or molten plastic can give a nasty burn.
It took me about 40 minutes, tops to make 20 metres of ladder line and cost just a few dollars.
Surely that's not too much to ask for one's hobby?

Welcome aboard,

Terry-k9tw gives good council....BEFORE you plug it in and turn it on...take the covers off...and give it a good "eyeball"
inspection. Obtain an "operators manual," and a "service manual." Both can be found at Gordon's-n6wk web site: n6wk.com.
Become familiar with the controls and tune up procedure(s). Buy or better yet...build a dummy load..you're going to need
one.

  Ken Kemski-k4eaa has a very good web site: k4eaa.com   LOTS of good stuff there.

If in doubt on your inspection results...feel free to ask...it's better that "letting the smoke out!"
Radio smoke is expensive.

  Also, it is customary here to sign your post(s) with at least your first name, and your call(if any).

OK so the new person builds a classic center fed Zepp. Now how does he get the tuned feeders in the shack whether he uses open wire or window line? It aint easy.

Old QST articles and ARRL handbooks show the tuned feeders terminate on large porcelain standoffs on the house under the eaves and then nice drip loops and then thru porcelain feed thru tubes thru the wall and the Balanced Tuner is mounted right there on the inside surface of the wall and the Transmitter is sitting on a table directly below the Tuner. So you have less than a foot of tuned feeder to the Tuner and two or three feet of coax run to the transmitter. Maybe in the 1950s unfinished attic shack? My first one in late 50s was exactly this. Many blissful hours spent in that attic with homebrew and converted WW2 army surplus and heathkit and knight kit gear. .

So the QST/ARRL depiction is an ideal installation, but very few shacks like that today. Just isnt the real world.

Often 25 to 50 feet or more after penetrating outside wall to get to the shack in the basement, den, bedroom with all finished walls and ceilings and no access to space between the floor joist etc. Large ,modern homes with finished walls and ceilings are pretty common state side.

Window line could be used in lieu of open wire feeders and routed to the shack as not as difficult to stand off along the route to the shack, but again almost impossible to snake and pull any distance.

So what do they really do today? They mount a 4:1 balun on outside wall in weather proof housing and end the tuned feeders (open wire or window type) at the exterior wall of the house. They now transition to coax and lots of variation here as to the type including some who parallel coaxes. Paralleling two runs of RG-8 or LMR-400 and using just the center conductors presents a balanced transition with less loss. Wont be 50 ohms but it does work.

Now most of these coax runs present a dilema. They will use relatively long runs of coax from the balun to the Tuner remotely located at the shack operating position. Now you have the high losses to content with that the high SWR on this coax presents. Can be as much as 10 dB loss in 25 to 30 feet of coax. Probably parallel coax is the best solution, but not everyone understands and uses this method of transition.

An option for all of this is a remote controlled Tuner at the exterior wall entry point, but these units dont come cheap and if you cant homebrew a Z match try building gear trains and position sensors and limit switches. I am not talking an auto tuner just a remote controlled balanced tuner.

So I suspect that Coax fed multiband antennas will continue to be the norm and the G5RV and OCF dipoles handle this much better than trying to feed a center fed Zepp with coax or to multiband a coax fed resonant dipole with a T-match Tuner.

Terry K9TW.

I was trying to very quickly get Rons attention to get the damn Heater switch turned off. Why would anyone troubleshooting a rig keying problem have the heater switch on?

And sure didnt want Ron to re-fuse the rig and try burning up the Plate choke or the HV rectifier board, or the Power transformer.

I am sorry and should have let it go. No way for me to know if Mike or anyone else was monitoring and could stop Ron from further damaging his rig. Felt like could not just sit on sideline and watch him do this.

I apologize to Mike if it looked like to one or more of our members that I was chastising Mike. We can all have professional differences but none exist related to this thread.

TURN THE HEATER SWITCH OFF MAN!

Why would you have the filaments on when troubleshooting a relay keying problem? There is no reason to have the heaters on until a few minutes before ready to load and transmit. Tubes only have so much life and running heaters all the time is not necessary.

If heaters are off then can be no cathode emission and if you lose cut-off or operating bias there will be no Plate current.

Likely you have lost the final tubes. They do not like thermal run away. How did you see the plate glow? Do you have the PA cage cover off? If so why? Have to be very careful with 900vdc present here.

Will let Mike help you trouble shoot this problem as well as the relay keying issues. Not likely related.

Just do not put heaters back on while working on the relay keying problem.

Hi Ron,

Have you tried grounding pin 2 on the MIC socket to see if the
relays energize? Pin 2 on the MIC socket is in parallel with the
SEND switch.

The meter switch settings are not enabled in receive. The 820 has

to switch to transmit (relay on the RELAY Unit) must energize for
the meter switch settings to work.

Steve,

  I have the 5 pc version...but I did get a real good deal on an NOS tv alignment set...this had everything I could possibly need,
especially some long shafted tools to get to some on the tuning coils...ie..T-4 on the 830 RF board...as this tool is flexible.
It was actually rather cheap...$30.00.

  Gordon's method sounds fine...about heating the tool...I have not used that method...but I trust his judgement,,,he's been at
this a lot longer than I have..hihi. I have several different coil slugs that are found on/in the KW hybrids...I use them to "fine tune"
my exacto knife approach as the slugs are junk(broken in half)...and I can observe them under my magnified light..remember...
use "decaf" coffee...those damn blades are sharp!

  I am shooting from the hip here...as I don't have a schematic in front of me...but with all else being equal...there maybe
some "crud" on the associated band switch contact points...as the "cal signal" I believe is inserted after L-41..(antenna step xfmr)
so should eliminate that as a possible problem. What is the difference between the "S" meter readings? They will tend to decrease
as the band changes go higher in frequency...but should NOT fall off from say, "S-9" on 20M to "S-3" on 10M

  I do not want to steer you in the wrong direction...others here have WAY more diagnostic skills than I do...so, I shall reserve
my recommendation to what my limited knowledge allows me to do

   hey Mo.....

I have the rig apart, now. I am waiting on Kens couples before i power up again. The plastic coupler on the band switch is broke. i was able to tighten up a bit as the screws were loose as well. Then when i was going through it again, i noticed that one of the set screws was now hanging out...by a thread. (haha) so i pulled that screw out, others are loose because the plastic scratched. i dont want to risk having a screw fall out when 900 volts is on. so once that is fixed, i will clean the contacts again (also will swap out the resistors on the final board and change the driver) THEN I will start recking the alignment again . All looked pretty good with the cal signal all close to S9...except 10 MHZ , like I said was really low S2 or 3 i think.
I found a little plastic rod in my sons lego stuff. It fits down into the can nice. Its short, so I glued into a tube used from a can of compressed air. I will carve and file tomorrow and try for fit. where did you find the NOS tools at? Amazon, Ebay? does it have a name or part number?

Thanks porcupine

I'm planning on coming through a window, actually. Basically a small, insulated box the width of the window, with storm seal top, bottom, and sides to catch the draft. Thin plywood over a block of 6-inch styrofoam, with a couple of pieces of 1" PVC pipe and a couple of flanges for a pass-through.

Fill the pipes with silicone, the non-setting kind, to keep out water and cut the breeze into the house, A couple of pieces of rubber sheet to cover the ends of the holes and to keep the silicone inside. Snip a slit in the rubber (scavenged from an old tractor inner tube, that's thick and should provide material for about five hundred of these...) to shove the wires through.

The spacing between the two pieces of pipe will be the same as the separation of the ladder line. Then in to the balanced line connectors on the antenna tuner, and out via a pigtail to the rig. I'll keep the tuner on bypass most of the time, I suspect. Shouldn't need much to load the Kenwood into an inverted V or whatever.

I plan on having several sorts of antenna, since that's the thing I -can- do to make the biggest difference in the performance of the whole rig anyway. Besides, it's the most fun part, tinkering. Can't do much with the insides of the radio, so I like to mess about with he antenna.

> 25 to 30 feet of coax. Probably parallel coax is the best solution, but

I've been considering this exact thing, actually. I've a BUNCH of old 75 ohm television coax, and yes it is full braid shield stuff, not just a few wraps. I was wondering if there was any information about how that would behave, electrically, if the center conductors were used in a parallel balanced-line configuration. What would be the best thing to do with the braid? Ground it at the rig end? Ground it at the -antenna- end? Leave it unconnected at both ends? Grounded at both ends? (NOT! Ground loops are such a bugger.) Can't seem to find any information on this, but it sounds intriguing.

Might be something to sic the antenna analyzer on, when it's done. I'm expecting the last chip (from China) to arrive this week, and then I can finish the thing. Anybody here got data about this? I'd love to see it.

I am ecstatic about a cheap acquisition I made, an 1970's era PACE soldering/desoldering station. It came with the pumps working properly, good heating elements and tips in both irons - a nice fine-gauge one for the soldering station, and a desoldering tip in almost-new shape. Even

had the clean-out wire for it. Anyway, it has made SMD soldering almost a pleasure. The antenna analyzer is the first fully-SMD project I've attempted, and with the new iron to help I suspect that it will be followed by other goodies of a similar sort.

First, you need to know the microphone and audio impedance values/ranges
for both transceivers. You will find them listed on the specification
page in each transceiver's operator manual.

Next, you should go to the Heil website to compare their specifications
to the microphone/headphone specifications in the hybrid manual's spec
sheet. Consulting with Heil, the manufacturer, is the best route you
should take.

I think you are Red and perhaps now Black and Blue!

Your rig and you can chose to run with heaters on at all times if you want. Folks do but I would not. Lots of rigs with no heater switch. KW provided it to facilitate mobile operation to lessen drain on battery.

How did you see the plates glowing red? Were you looking inside PA cage for source of relay keying issue?

Was the radio working in receive mode during this 10 minute period before they turned red?

If no receive are you sure the relays are not keyed and rig is in standing TX mode?

If good receive then relays not keyed and about only way for finals to take off in receive mode is a problem with cut off bias.

Terry

75 ohm will work just fine.

Here is what you need to help decide about grounding just one end of your transition coax. Also take a look at the losses. Not a perfect solution but much better than just transitioning to a long single coax run to the Tuner in the shack.

45103. Following instructions

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-06 14:24:55 UTC
From: Mike
Topic: 45103 Message: 45103

I don't mean any disrespect to anyone with what I am going to say.

I see a lot of senseless confusion that occurs because members asking for help don't seem to use common sense and follow simple instructions.

Quite often members don't seem to take the time to read/study the operator's manual before they attempt to operate their hybrid. A lot of operator error problem can be solved it the member read/studied the operator's manual. If the manual was not included in the sale, download it from Gordon's website

www.n6wk.com/kenwood/

and read/study it.

I also see where a lot of members who want to fix their hybrid but quite often do not have or even have access to basic test equipment. You can't fix your hybrid without some basic test equipment. I made a video showing some basic test equipment (see the following link):

http://www.n6wk.com/w5rkl/Test%20Equipment/

You also need to know how to properly and "safely" use the test equipment which includes having a thorough understanding of the proper safety precautions you MUST follow when working around HV. Many times we have stated, "There are voltages in the KW hybrid that can KILL YOU!" so don't ignore the importance of safety!! YOUR LIFE depends on it!!

Quite often members asking for help seem to leave out a lot of important information in their request for help. Here are a few examples of important information left out of a member's post asking for help:

1. Do you have and have you read the operator AND service manuals?
2. What level of electronic knowledge along with any troubleshooting and repair skills do you have?
3. What test equipment do you have and do you know how to properly and safely use the test equipment?
4. Do you have a dummy load?
5. Have you properly set the controls according to the operator's manual?
6. What components have you replaced, if any, before you asked for help?
7. Have you explained, in detail, everything about the problem you are experiencing? We can't read your mind.

If you are given instructions to follow, FOLLOW them, don't do anything else! Quite often I've seen members create more problems by doing something they were not instructed to do. Here's an example of not following instructions:

"I read where I should also do ..... so in addition to your instructions I also did that. Now the transmitter no longer keys. What's wrong now?"

What's wrong NOW? It's simple, you have now created more problems or made the problem worse because you did something you were not instructed to do!

I, as well as others who are providing help, understand the hybrid you have is yours to do with what ever and how ever you please. However, when you ask us for help and are given instructions to follow, don't blame us when we point out things you should not have done that have made the problem worse!

I would agree with this mostly. However I don't advise someone to blindly follow advise that doesn't make sense to them. Make sure you understand the reasoning behind the expert's advise. If it does not make sense to you, you should have the elmer explain there reasoning. Elmer's should also be patient with this process. It is a part of the learning process -- the most important one. I have had elmer's loose their cool more than once.

This also clears miscommunication, and prevents one from being led down a rabbit hole.

Terry did a great job in this respect -- Kudos :D

My $.02,
Chris KQ6UP

45105. What is the Big Deal?

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)

We have covered this before on this forum so here goes for last time from me. Got an email that went like this:

I have a 1/2 wavelength 80 meter dipole that I feed with approx 100 feet of good RG8X and use my MFJ tuner on all bands. It loads great on 80 meters and I can load it on 20 meters and make contacts all the time including DX. What is the big deal about using coax instead of ladder line as this ongoing thread keeps harping about. If you old timers think it is so bad why are so many new hams doing this when it works just fine for them?

Here is the "Big Deal" from old timers perspective:

Yes you can use Coax feed and multiband your resonant dipole. Yes your antenna better work well on 80 meters. Yes you can load on 20 meters with your MFJ T-match tuner. However, here is what you are doing for sake of convenience that coax feed allows:.

Using a 1/2 wave 80 meter dipole (or 40 meter) results in a wide range of impedance at the center feed point. This results in a mismatch between the coax and antenna and your tuner cannot change that. Depending on the band can range from 100 ohms to thousands of ohms and it isnt pure R. It will have a reactive component as well. So you will have a mismatch from your 50 ohm coax to this impedance that results in very high SWR (not the loathsome 2:1). On 20 meters it could be as high a 4000 ohms. If you have a antenna analyzer can measure it. If 4000 ohms then 4000/50 = 80:1 SWR. This high SWR is a problem because of the additional loss per foot with coax feed line.

Lets assume on 20 meters the antenna feedpoint of your 80 meter dipole looks like 1200 ohms.1200/50 = 24:1 SWR.

What will be the losses be at 14.2mhz with 100 watts from your KW hybrid?

1. 100 ft of RG8X has approx 1.0 db matched loss at 14.2mhz (this is the attenuation per foot for given frequency).1.0 dB loss is not detectable on receiving end. No Big Deal.

2. 24:1 SWR results in additional loss of 5.0 dB.

3. 5 dB + 1 dB = 6.0 dB loss. Total loss is approx 6.0 dB.

4. A 6 dB loss with 100 watts output from your Hybrid results in 24 watts at the antenna. This is the Big Deal.

5. You are making contacts on 20 meters with 24 watts. If you are having fun with 24 watts then there is no Big Deal. That is for you to decide. I suspect you are not aware you are operating with "accidental" qrp power? Ok not true QRP but you get the point.

Here is comparison with Balanced Feeders;

1. 450 ohm ladder line matched loss will be approx 0.12 dB and not 1.0 dB.

2. 24:1 SWR loss will be 1.0 dB for a total loss of approx 1.12 dB and not 6.0 dB.

3. Power available now with a 1.12 dB loss is approx 78 watts to the antenna.

4. For 600 ohm line power will be approx 83 watts and for 300 line ohm it will be approx 64 watts.

5. Summary.... 50 ohm coax = 24 watts and 450 ladder line = 78 watts on 20 meters. I think that is a Big Deal or at least significant.

Again no one said what you and other new and old hams alike are doing wont work. The question is what is the definition of Work as it relates to efficiency..

The point of the long ongoing thread about balanced feeders and balanced tuners like the Z-match was to ensure that you understand this and if you are making contacts on all the bands you like to operate on and dont want the hassle of using balanced feeders and figuring out how to get them to your operating position in the house then there is no Big Deal.

ARRL and others have charts and on line calculators you can use to determine line and SWR losses of various feed lines.

Terry K9TW .

Mike, I have been leaving my heating filaments on per the admonition of several old timers in order too avoid thermal stress that can cause the heater to fail before emisivity falls off. I tried to start a thread along these lines, but I don't recall you weighing in.

Just curious as to your pro/con reasoning here.

My admonishment to Ron about heaters off was more related to how to configure the rig for troubleshooting on the bench and not so much about tube life which can argue either way. I will let Mike address that.

I have a lot of experience, but I always put a rig on the service bench in a position that ensures the least amount of damage on initial power on. Things like:

1. Heater off
2. Car Level pot full CCW
3. Mic gain pot full CCW
4. Send switch to Receive
5. Dummy load connected to SO-239
6. Remote speaker connected (I dont like the audio output amp to be open ended)

I dont want any inadvertent transmit to occur on initial power on.

If I am in the PA cage I mesh the air variable cap plates to avoid accidental damage..

Just little precautions. Maybe anal, but I try to minimize surprises.

I look at every Ebay picture of KW hybrids listed and most make me sick.
1. Power and heaters switch on
2. Send switch flipped to Send
3. In CW or Tune mode
4. CAR pot advanced.
5. Meter in ALC or RF so no idea where IP is at
6. No evidence of dummy load connected.
7. How long powered on like this?

The ad states " Radio powers on but unable to test further"

I dont want any of those radios!

Just me.

Your rig and you can chose to run with heaters on at all times if you want. Folks do but I would not. Lots of rigs with no heater switch. KW provided it to facilitate mobile operation to lessen drain on battery.

How did you see the plates glowing red? Were you looking inside PA cage for source of relay keying issue?

Was the radio working in receive mode during this 10 minute period before they turned red?

If no receive are you sure the relays are not keyed and rig is in standing TX mode?

If good receive then relays not keyed and about only way for finals to take! off in receive mode is a problem with cut off bias.

Terry

Hi Ron,

Have you tried grounding pin 2 on the MIC socket to see if the relays energize? Pin 2 on the MIC socket is in parallel with the SEND switch.

The meter switch settings are not enabled in receive. The 820 has to switch to transmit (relay on the RELAY Unit) must energize for the meter switch settings to work.

As someone told me over 30 years ago when I was getting into this radio lark, if you turn the heaters on all the time you'll eventually burn off the cathode coating.

But, if you switch them off and only switch them on when you want to transmit, the thermal cycling will eventually cause the heater to fail.

And in either case, you *will* shorten the life of the valve by possibly as much as a couple of hours for every ten years of operation :-D

45110. Re: [TS-520_820_530_830] Following instructions

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-06 18:22:51 UTC
From: W5RKL
Topic: 45103 Message: 45110

Yes, I could have included a statement that said, "follow instructions that are backed up with actual facts and explanations why you should perform the instructions". I did not include that statement or something similar because more often than not, instructions provided to member on this group, more often that not, include facts and supporting statements why the instructions should be followed. Yes, I know there are some suggestions that are pure non-sense and out right wrong but when those appear, the factual statement/instructions point those out and why they should not be followed.

Something I have a difficult time understanding is a ham who has no basic knowledge of electronics, can't read a schematic, has never performed any troubleshooting, and doesn't have nor has ever used test equipment, believes they can repair their sophisticated KW hybrid by asking a few questions. While they may be "trolling" for answers so they can the answers to someone else who is experienced, I suspect most of the time that is not the case. There has been many times where I have seen members say, "I don't have the experienced/knowledge but I want to learn". That's a great idea but unless that member(s) actually spend time reading and studying and asking questions about topics they are having troubles understanding, the statement is nothing more than words on a computer screen. Learning electronics not something you learn overnight, over a weekend, or even within 6 moths. It takes time to study and that means reading reference material that has been provided many times on this group. I don't know how one is going to learn if they are not interested in reading/studying? Maybe because, as many thing are today, "There's not an ap for that!!".

I'm no expert, I have never said I was. However, I didn't learn what I know by sitting on my butt and having someone else do the work. I still read/study/review the basic subjects such as resistors, capacitors, inductors, power supplies, receivers, transmitters, and other electronic subjects. Again, a person will not learn it overnight, over a weekend, or even after 6 months. It takes time to study and ask questions.

Again, I mean no disrespect towards anyone.

The heater switch was OFF yet the final tube plates glowed RED? Are you sure the HEATER switch was OFF?.

Have you checked the HEATER switch to see if it actually opens the circuit when pressed to the OFF position? If the switch is good the filaments will be dark in the OFF position but glow in the ON position. The tubes cannot conduct if the filaments are turned OFF.

Also, have you verified the presents of bias voltage at the output of the -C supply and at the grids of each final tube? As Terry said, and I agree, the only way the final tubes will conduct to saturation levels in receive is if the bias supply has failed, which removes cut off bias from the bias circuit and ultimately from the final tube grids.

I may have missed it but why did you change the final tubes? What troubleshooting results indicated the final tubes needed to be replaced?

I have made these same observations. If newbies don't want to follow the instructions they should not be messing with these radios.

If you don't want buy the necessary test equipment this is not a hobby for you!

Subject: Re: [TS-520_820_530_830] Following instructions

Yes, I could have included a statement that said, "follow instructions that are backed up with actual facts and explanations why you should perform the instructions". I did not include that statement or something similar because more often than not, instructions provided to member on this group, more often that not, include facts and supporting statements why the instructions should be followed. Yes, I know there are some suggestions that are pure non-sense and out right wrong but when those appear, the factual statement/instructions point those out and why they should not be followed.

Something I have a difficult time understanding is a ham who has no basic knowledge of electronics, can't read a schematic, has never performed any troubleshooting, and doesn't have nor has ever used test equipment, believes they can repair their sophisticated KW hybrid by asking a few questions. While they may be "trolling" for answers so they can the answers to someone else who is experienced, I suspect most of the time that is not the case. There has been many times where I have seen members say, "I don't have the experienced/knowledge but I want to learn". That's a great idea but unless that member(s) actually spend time reading and studying and asking questions about topics they are having troubles understanding, the statement is nothing more than words on a computer screen. Learning electronics not something you learn overnight, over a weekend, or even within 6 moths. It takes time to study and that means reading reference material that has been provided many times on this group. I don't know how one is going to learn if they are not interested in reading/studying? Maybe because, as many thing are today, "There's not an ap for that!!".

I'm no expert, I have never said I was. However, I didn't learn what I know by sitting on my butt and having someone else do the work. Spark gap.

Make some pointy copper/brass spikes (should look like a copper nail)m
or you can use some copper-clad carbon arc light or welding rod. One
goes on the ladder line wire, the other gets tied to a solid ground with
about an eighth of an inch between the points. Of course you need one
pair for each leg of the ladder.

Or you can use some non-resistor spark plugs (check tractor supply
places if your local auto parts store doesn't have any non-resistor
types, or maybe chainsaw/lawnmower repair shops), one per leg, leading
to ground on one side of the gap.

Either way, the idea is to give the bolt an easier path to ground than
the one presented by your radio and its ground.

Greg,

I'm definitely not as experienced as Terry, but I would suggest that you also check out Array Solutions AS-305H Arrestor. It also drains static which can also be very harmful (even with coax feeds here in SW Oklahoma!!) to solid state rigs. Not so much the hybrids, but could damage the front end, I guess. My coaxes will draw an arc every once in a while (as does the 300 ohm window line) if I don't have these in line.

The only positive solution for lightning protection is to disconnect the feed line from the shack where it enters the building. And move the feedline as far from the building as possible.

I spent 4 years doing lightning protection on telescopes on top of mountains in Arizona. Look at the photos of lightning at Kitt Peak (KPNO).

There are areas of the US that are lightning prone. And lightning is completely unpredictable.

Don't say that disconnection the feedline is too inconvenient. It's the cheapest and most positive solution.

Spark gap.

Make some pointy copper/brass spikes (should look like a copper nail)m
or you can use some copper-clad carbon arc light or welding rod. One
goes on the ladder line wire, the other gets tied to a solid ground with
about an eighth of an inch between the points. Of course you need one
pair for each leg of the ladder.

Or you can use some non-resistor spark plugs (check tractor supply
places if your local auto parts store doesn't have any non-resistor
types, or maybe chainsaw/lawnmower repair shops), one per leg, leading
to ground on one side of the gap.

Either way, the idea is to give the bolt an easier path to ground than
the one presented by your radio and its ground.

Topic: 45058 Message: 45118

When I owned my TS-820S, I left the HEATER switch set to ON all the time. The TS-520SE I use to own many years ago, did not have a HEATER switch since the 520SE is designed to operate from 120/240VAC ONLY. Kenwood put the HEATER switch in the TS-530 and TS-830.The reference to the HEATER switch in the manual simply states in the manuals that the HEATER switch turns all 3 transmitting tube filaments ON, nothing more.

Heathkit's Apache TX-1 and Heathkit's Marauder HX-10 transmitters both had a separate filament transformers that provided a constant 6.3VAC to the VFO's filaments as long as the main power plug was plugged into the wall outlet. I have both transmitters and ran them for years and never experienced a filament failure or reduced emission due to constant filament power.

Most of my ham gear consist of all vacuum tubes with only 2 all solid state transceivers (Yaesu FT-757GX and FT-857D) and two all solid state receivers (Heathkit SB-303 and a Kenwood R-599D). The tube filaments in the vacuum tube gear are all powered ON the moment the main power switch it turned ON. I have never experienced any problems with power supplies or with filament failure or thermionic emission failure in any vacuum tube used in my gear. I have experienced failures in vacuum tubes but not due to filament issues but rather due to excessive gas collecting in a 6146 because it sat for "20 years" in my HW-101 (the original owner let it sit in his garage for 20 years with no power applied). The failure occurred after 3 days of testing. Surprisingly the 6146As produced full output but after 3 days one 6146A arced when keyed, drive set to minimum. The arcing blew the supply's breaker (HP-23A), no damage to any component in the supply or the HW-101. Replaced both 6146As, problem solved.

Whether you set the KW hybrid's HEATER switch to ON or OFF is entirely up to you. I doubt you will experience filament failure due to stressing the filament by powering the filaments ON and OFF each time you power up your KW hybrid or if you leave the HEATER switch set to ON while you are using your hybrid.

In the old days the Handbooks all showed a design that used a non-resistor spark connected from each feeder leg to ground and the gap set close. Hard to find a non-resistor spark plug today.

We also installed 100k ohm 2 watt resistors from each feeder leg to ground and sometimes a 2.5 mhy rf choke in parallel with each resistor. These served as static bleeds.

I suppose a larger wire wound resistor would work if not self resonant on bands you operate on. Would combine the resistance and inductance in one device.

Today ICE and others sell open wire protective devices. Never seen a schematic for them, but likely have resistors and/or chokes for static bleed and then modern vacuum arc gaps for nearby lightning.

I dont run tuned feeders today. Have Mosley CL-33 triband beam coax fed and a 10 to 80 meter OCF dipole coax fed with 4:1 current balun and choke balun at the offset feed point. I like the fast QSY capability so no Tuners for me anymore.
I protect my coax feed lines with Alpha Delta arrestors mounted on a copper plate in a distribution panel on wall outside the house tied to 3 driven grounds and the utility neutral. Inside the house at operating position I have Alpha Delta antenna switches that have arc gaps and a ground position. So far no problems with nearby lightning.

If I am home I unscrew coax off the rigs SO-239. Just did so last night as nasty storm came thru. I dont care if I lose the big screen plasma, but dont hurt my TS-830s!

Spark gap.

Make some pointy copper/brass spikes (should look like a copper nail)m
or you can use some copper-clad carbon arc light or welding rod. One
goes on the ladder line wire, the other gets tied to a solid ground with
about an eighth of an inch between the points. Of course you need one
pair for each leg of the ladder.

Or you can use some non-resistor spark plugs (check tractor supply places if your local auto parts store doesn't have any non-resistor types, or maybe chainsaw/lawnmower repair shops), one per leg, leading to ground on one side of the gap.

Either way, the idea is to give the bolt an easier path to ground than the one presented by your radio and its ground.

That's what I do. I have only one antenna, a 40 meter inverted vee, hanging from a pine tree limb. I disconnect if thunderstorms are forecast in our area. Lightning struck the pine tree last year. The blot flowed down the back side of the tree, crossed over "through" the tree to the front then continued down the front side the changed directions and ran up the limb and jumped 4 feet to the 1:1 balun's ground strap. The bolt discharged down the braid and dissipated into the ground through the PL-259. The coax was not damaged. The only damage was the point where the center conductor was soldered to the PL-259. I removed the cable from the PL-259, cut off the bad area, cleaned up the connector, and put the coax cable back in and soldered it to the PL-259. It's been in use ever since. There are black carbon tracks on the balun's SO-239 but the balun itself was not damaged.

I agree, lighting is unpredictable. It is important to drain the charge build up which helps reduce the chances of a strike. If you are interested in reading about grounding and lightning protection, Tom W8JI, has a nice webpage that discusses with picture on this subject:

www.w8ji.com

You might find that the problem there is that the "necessary test equipment" is 2x - 3x the cost of the rig and not a viable option at that point for many --whether for monetary reasons or because of physical ability. We are, IMO, destined to become a dwindling elitist organization if we don't become major proponents of a larger and more cost effect group of repair facilities.

Subject: Re: [TS-520_820_530_830] Following instructions

Yes, I could have included a statement that said, "follow instructions that are backed up with actual facts and explanations why you should perform the instructions". I did not include that statement or something similar because more often than not, instructions provided to member on this group, more often that not, include facts and supporting statements why the instructions should be followed. Yes, I know there are some suggestions that are pure non-sense and out right wrong but when those appear, the factual statement/instructions point those out and why they should not be followed.

Something I have a difficult time understanding is a ham who has no basic knowledge of electronics, can't read a schematic, has never performed any troubleshooting, and doesn't have nor has ever used test equipment, believes they can repair their sophisticated KW hybrid by asking a few questions. While they may be "trolling" for answers so they can the answers to someone else who is experienced, I suspect most of the time that is not the case. There has been many times where I have seen members say, "I don't have the experienced/knowledge but I want to learn". That's a great idea but unless that member(s) actually spend time reading and studying and asking questions about topics they are having troubles understanding, the statement is nothing more than words on a computer screen.

Learning electronics not something you learn overnight, over a weekend, or even within 6 moths. It takes time to study and that means reading reference material that has been provided many times on this group. I don't know how one is going to learn if they are not interested in reading/studying? Maybe because, as many thing are today, "There's not an ap for that!!".

I'm no expert, I have never said I was. However, I didn't learn what I know by sitting on my butt and having someone else do the work. I still read/study/review the basic subjects such as resistors, capacitors, inductors, power supplies, receivers, transmitters, and other electronic subjects. Again, a person will not learn it overnight, over a weekend, or even after 6 months. It takes time to study and ask questions.

Again, I mean no disrespect towards anyone.
